Consult: Schouler, *The Law of Personal Property* (3d ed., Boston, 1896); Brantley, *Principles of the Law of Personal Property* (San Francisco, 1890); Goodeve, *Modern Law of Personal Property* (3d ed., London, 1899); Williams, *Principles of the Law of Personal Property for the Use of Students in Conveyancing* (15th ed., London, 1900).

PERSONAL REPRESENTATIVE. Besides its general sense of one who succeeds to or represents another in the enjoyment or possession of rights or property by reason of some relationship existing between them, the term personal representative is specifically used in law to designate the person who as executor or administrator administers the estate of another. In the general sense of the word it is applied to those who represent others in conducting transactions, as one acting under a power of attorney to vote stock, and also to those who succeed to property by assignment, as the assignee of a lessee for years, and sometimes in wills for those who are technically called next of kin (q.v.), according to the statute of distribution, and, in its broadest use, even all persons who stand in the place of another and represent his interests, respecting his property, whether transferred to them by law or by his act.

Primarily and usually, however, the term is used to designate only executors or administrators as officially administering the estate of the deceased, and in that capacity protecting it from dissipation or waste, as well as paying out of it the debts of the decedent, and distributing the surplus, if any. Unlike the heir under the civil law the personal representative is not liable for any debts of the decedent, except to the extent of the assets received by him; and neither is he now entitled to any surplus remaining after the payment of the obligations of the estate. His duties, and the method and form of his administration are usually particularly prescribed by statute. See ADMINISTRATION; EXECUTOR; DISTRIBUTION, etc., and compare KIN, NEXT OF, and HEIR.

PERSONIFICATION (from Lat. *persona*, person + *facere*, to make). A figure of rhetoric by which inanimate objects, or mere abstract conceptions, are invested with the forms and attributes of conscious life. See RHETORIC, FIGURES OF; METAPHOR.

PERSOON, pâr'sōn, CHRISTIAN HENDRIK (1755-1837). A Dutch physician and botanist, born at the Cape of Good Hope, Africa. He was educated in Holland and practiced his profession for a number of years in Germany. He went to Paris about 1802, where he published several interesting works on cryptogamous plants; also, a *Synopsis of Plants* in two volumes. The titles of his principal works are: *Observationes Mycologicæ* (1796); *Synopsis Methodica Fungorum* (1801); *Icones Pictæ Speciorum Rariorum Fungorum* (1803-08); *Synopsis Plantarum* (2 vols., 1805-07). The Australian genus Persoonia is named in his honor. It embraces about 60 species, some of which are valuable timber trees.

PERSPECTIVE (Fr. *perspective*, from Lat. *perspectus*, p.p. of *perspicere*, to see through, from *per*, through + *specere*, to see). The art of representing natural objects upon a plane surface in such manner that the representation shall affect the eye in the same way as the objects themselves. The distance and position of objects affect both their distinctness and apparent form, giving rise to a subdivision of perspective into *linear* perspective, which is strictly scientific and a branch of applied geometry, and which, as its name denotes, considers exclusively the effect produced by the position and distance of the observer upon the apparent *form* and *grouping* of objects; and *aerial* perspective, which confines itself to their distinctness, as modified by distance and light, and belongs to the non-scientific sphere of pictorial representation. After the 'scope' (i.e. the number of objects to be introduced, and the distance at which they are to be viewed) of the picture has been determined, and before the design is commenced, it is necessary to draw upon perspective plan three lines: (1) The *base line*, or *ground line*, which limits the sketch toward the

spectator, and is the base line of the picture. (2) The *horizontal line*, which represents the ordinary position of the sensible horizon. The height of the horizontal line is about one third of the height of the picture, when the sketcher is placed at or a little above the level of the horizon; but it may rise in a degree corresponding to his increase of elevation till it reaches near to the top of the perspective plan. The general rule is to have a high horizontal line when the view is taken, or supposed to be taken, from an eminence; but when the station is on a level, either actual or assumed, the horizontal line must be low. The horizontal line in nearly all cases is supposed to be level with the spectator's eye. (3) The *vertical line*, which is drawn from the supposed position of the sketcher, perpendicular to the *ground* and *horizontal* lines, meeting the latter in a point which is called the *point of sight*, or centre of the picture. The vertical line has no representative in nature, and is merely a mechanical adjunct to the construction of the picture, all vertical lines in nature being parallel to it in the picture. The point of sight, being the point directly opposite to the observer, is often placed in the centre of the picture; but we very frequently find it on the right or left side, though always, of course, on the horizontal line. All lines which in nature are perpendicular to the ground line, or to a vertical plane which is raised upon it as a base, meet in the point of sight, which is thus their *vanishing point* (see the line of the tops and bottoms of the pillars in Fig. 1). The *points of distance* are two points in the horizontal line on each side of the point of sight, and in a 'direct' sketch are at a distance from it equal to the horizontal distance of the sketcher's eye from the ground line. The equality of distance of these points from the point of sight is not, however, necessary, as it occurs only in those cases where the lines, of which the points of distance are the *vanishing points*, are inclined (in nature) at an angle of 45° to the base line; but, in all cases, the two points of distance are about twice as far apart as the eye is from the picture. One important use of the points of distance is to define the distance of objects in a row (Fig. 1) from each other. For this purpose, two points of distance are not necessary, as, when the position of one pillar is found, that of the opposite is at once obtained by drawing a line parallel to the base or ground line.

There are many other groups of parallel lines in a picture which have different situations, and therefore different vanishing points. Such lines with their vanishing points (called, for distinction's sake, *accidental points*) are represented in Fig. 2. If the accidental point is above the horizontal line, it is called the *accidental point aërial*—if below, the *accidental point terrestrial*; and a little consideration makes it evident that these points may or may not be situated within the plane of the picture. Such are the points and lines necessary for the construction of a plan in true perspective; and from the above explanation, we may deduce the two general principles: (1) That all parallel straight lines in nature are no longer parallel when projected on the perspective plane, but meet in a point which is called the vanishing point, and is some one of the three above described, unless these lines happen to be also parallel to the ground line or the vertical line, in which case they remain parallel when transferred to the picture; and (2) that since the bodies drawn below the horizontal line are seen as if from above, those above as if from below, and those to the right and left of the point of sight as if observed from the left and right, it follows that straight lines which in the picture are above the horizontal line lower themselves, and those below raise themselves to it; those to the left, following the same law, direct themselves to the right, and vice versa.

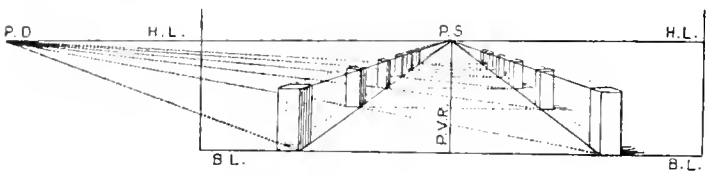

Fig. 1.

Illustrating the more important points and lines. PVR is the principal visual ray.

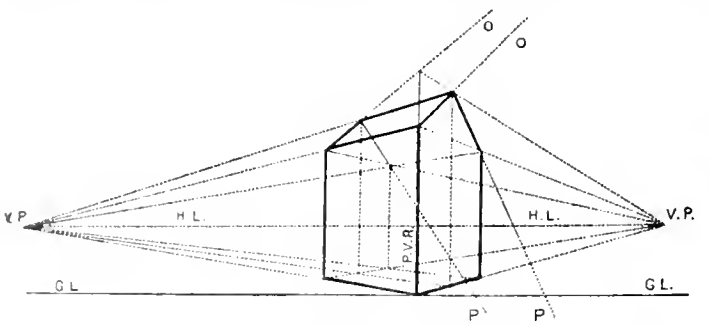

Fig. 2.

The lines OO converge to the accidental point aërial, and PP to the accidental point terrestrial.

Besides the more usual angular perspective there is the *bird's-eye perspective*, when the eye is taken up to an imaginary high level: the *curvilinear* or panoramic perspective, in which the surface of projection is a concave cylinder: and the *oblique* perspective, with its triple horizons and vanishing points.

Aërial perspective consists in a modulation of the brightness and colors of objects in accordance with the state of the atmosphere, the depth of the body in the perspective plane (i.e. distance in nature from the ground line), and other accidents of place and time. As the distance of objects increases, their illuminated parts are made less brilliant, and their shaded parts more feeble. The bluish tint imparted by a large mass of the atmosphere to the bodies seen through it is fre-

quently imitated by the mixing of a slight tint of blue with the colors to be applied; a yellow object thus assumes a greenish tint; a red one a violet tint, etc. The air, when charged with vapor, is represented by a diminution of the brightness of colors, and by the grayish tint imparted to them.

Architectural perspective is simply the application of linear perspective to architectural drawing. The plans, elevations, and sections by which buildings are represented in the working drawings are orthographic projections, which give the correct geometric and dimensional relations of the various parts of the building shown, but present in each case only two dimensions, and do not exhibit the natural aspect of the structure as it appears to the eye from any given point of view. This deficiency is supplied by the perspectives, which show its appearance as seen from one or another point of view, all three dimensions being represented, but with the foreshortenings and angular distortions of its actual appearance from the given point. It is customary to make perspectives not merely of the exterior of a projected or executed building, but also of the more important interior portions. See DRAWING.

HISTORY. Knowledge of perspective in all its branches is comparatively modern.

Oriental art knew nothing of any branch. A glance at Egyptian and Assyrian reliefs shows that the most elementary principles were ignored. Buildings and trees were laid flat on the ground or stood up in front view; the figures were placed one on top of the other instead of on different planes.

Greek art first studied and solved some of the mysteries of linear perspective, but it is doubtful that the Greeks ever got beyond the architectural form into the plastic and pictorial forms. This step was reserved for the more realistic art of the Alexandrian and especially the Roman age. The frescoes at Pompeii often exhibit an elaborate attempt to draw buildings in perspective with varying degrees of unsuccess.

Renaissance art, however, attacked almost immediately the question of linear perspective in all its branches. Such men as the Pollainolo and Andrea del Castagno, Melozzo and Mantegna revelled in their ability to overcome its difficulties. After playing with architectural design, with both normal and abnormal base lines, they played with the foreshortening of figures. From painting the use of linear perspective crept into sculpture, especially through Donatello. During the fifteenth century aërial perspective appeared in the landscape backgrounds of the early Flemish painters, like the Van Eycks, whose use of oil colors gave the necessary element of depth, diffused luminosity, and softness. The highest development of aërial perspective, however, was accomplished mainly by the Venetians of the sixteenth century, like Paolo Veronese, and by Correggio.

BIBLIOGRAPHY. Early treatises are Houdin, *La perspective* (Paris, 1642); Alberti, *Deux livres sur la perspective* (Nuremberg, 1671). The subject is very fully treated in Ware, *Modern Perspective* (Boston, 1885). Consult also: Cloquet, *Nouveau traité élémentaire de perspective* (Paris, 1823); Herdman, *Curvilinear Perspective in Nature* (London, n. d.); Seeberger, *Principien der Perspektive* (7th ed., Munich, 1900); Checa, *La perspective* (Paris, 1900); La Gournerie, *Traité de perspective linéaire* (ib., 1898); Pratt, *Perspective*, including the *Projection of Shadows and Reflections* (London, 1901); Conz, *Lehrbuch der Perspektive* (2d ed., Stuttgart, 1902).

PERSPECTIVE. In mathematics, a term applied to figures, one of which is formed from another by a single central projection. Thus, if from a point S, exterior to two planes P and P', a pencil of rays pass through the vertices of a triangle ABC situated in plane P, these rays meet P' in the vertices of a triangle A'B'C' *in perspective* with the triangle ABC. In general, P cuts P', and the line of intersection is called the *axis* of perspective, the point S being called the *centre* of perspective. If the planes P and P' be brought into coincidence, the triangles, or other figures similarly related, are still said to be in perspective. In two perspective figures, a point or line of one corresponds to a unique point or line of the other, hence a curve and its projection are of the same order and the same class (see CURVE), e.g. a conic section is always projective, or in perspective with a conic section, although the species may not be the same. Many properties of perspective figures are demonstrated by means of the fundamental proposition: The anharmonic ratio (q.v.) of perspective ranges is constant. See PROJECTION.

PERSPECTIVE DRAWING. See DRAWING.

PER STIRPES (Lat., according to stocks). A term used in designating that succession to the property of a deceased person by which the descendants take 'by the stock or root of their race'; that is, by virtue of representing an ancestor who would have been entitled to take if alive. The term is used in opposition to the phrase *per capita*. By the general rule, where the descendants of the same deceased ancestor are of unequal degrees of relationship, they take *per stirpes*, instead of *per capita*. For example, if A dies, leaving three living children, B, C, and D, and three grandchildren, the children of his deceased child E, those descendants will take *per stirpes*, that is, the estate will be divided into four parts, each of the living children, B, C, and D, taking one part, and the three grandchildren taking the fourth part, which their ancestor, E, would have taken if alive. If there is real estate, the three grandchildren will become tenants in common of the whole, with the three living children, and will be entitled to one undivided fourth part thereof. In some States the above rule is not followed, and the statutes of each State should be consulted. See DESCENT; DISTRIBUTION; PER CAPITA; SUCCESSION.

PERTH, pĕrth. The capital of West Australia, situated on the north bank of the Swan River, 10 miles northeast of Freemantle, on the Eastern Railway, in the vicinity of the Victoria range of mountains, and surrounded by picturesque scenery (Map: Australia, B 5). It is the see of Anglican and Roman Catholic bishops. The most notable of the public buildings are the Government and Parliament houses. It received a marked influx of population during the last decade of the nineteenth century, owing to the discovery of gold in the district. Population, in 1890, 9617; estimated, in 1895, 19,600.

PERTH. The capital of Perthshire, Scotland, a city, royal and Parliamentary burgh, on the Tay, 45 miles northwest of Edinburgh (Map: Scotland, E 3). The charming scenery of the immediate vicinity, the Tay, sweeping southward along its eastern side, and the superb background of the Grampians, on the north, render the site of the 'Fair City' exceedingly beautiful; while the important rôle it has played in the history of the country claims for it a high rank among the cities of Scotland. The river is spanned by two handsome bridges, and there are two beautiful public parks, called the North and South Inches. Among the most interesting public buildings are the Church of Saint John (whence Saint Johnstown, or Saint John's Town, the old name of the city); the Episcopal Cathedral of Saint Ninian's; the county building; the town-house, part of which is as old as 1210; King James VI.'s Hospital; the infirmary; and the city prison. At the head of the South Inch stands the penitentiary, or general prison, where all criminals sentenced to imprisonment for long periods are confined. The town also contains a statue of Albert, Prince Consort, a public library, the museum of the Antiquarian Society, public seminaries, and other educational institutions. It has ink, glass, cotton, and dye works, iron foundries, breweries, linen and wincey manufactures, shipbuilding yards, distilleries, and extensive bleaching fields. The salmon fishery on the Tay is very valuable. The total quayage of Perth harbor is 1225 feet, and vessels of 200 tons can draw alongside. Perth has a charter as a royal burgh from King William the Lion (1165-1214). Perth was the scene of the murder of the Earl of Cornwall, by his brother Edward III., in 1336; of a combat between two Highland clans (1396), described in Scott's *Fair Maid of Perth;* of the assassination of James I. in 1437, notwithstanding the heroic action of Catharine Douglas, who died to prevent the entry of the murderers by making her arm do duty for the missing bar on the door; and of Knox's Reformation sermon. Population, in 1891, 30,000; in 1901, 32,872. Consult Peacock, *Perth: Its Annals and Archives* (London, 1849).

PERTH, Five Articles of. Certain articles agreed upon in a meeting of the General Assembly of the Church of Scotland, convened at Perth, by command of King James VI. (James I. of England) on August 25, 1618. They enjoined kneeling at the Lord's Supper; the observance of Christmas, Good Friday, Easter, and Pentecost; confirmation; and sanctioned the private administration of baptism and the Lord's Supper. They were highly obnoxious to the Scotch Presbyterians, not only because of their character, but because they were adopted without discussion in mere compliance with the will of the King. The General Assembly at Glasgow in 1638 declared that at Perth to have been 'unfair, unlawful, and null,' and condemned the five articles.

PERTH, George Drummond, Earl of (1807-1902). A British nobleman. He was born in London during the reign of George III. and consequently saw five monarchs occupy the throne of the United Kingdom. For a short time he served as an officer in the 93d Sutherland Highlanders, and, from 1853 till 1859, was a major in the Victoria Middlesex Rifles (Volunteer). Because of his ancestors he was chief of the Clan Drummond, 14th Earl of Perth, 6th Earl of Melfort, Viscount Melfort and Forth, Baron Drummond of Cargill, Baron Drummond of Stobhall and Montifex, Baron Drummond of Richertown, Castlemaine, and Galstown, hereditary Thane of Lennox, hereditary Steward of Monteith and Strathearn, Duc de Melfort, Comte de Lussan, and Baron de Valrose. When he died these titles were separated, as he left no direct male heir.

PERTH AMBOY, ăm-boi' or ăm'boi. A city and port of entry in Middlesex County, N. J., 15 miles south of Newark; on Raritan Bay, at the mouth of the Raritan River, and on the Lehigh Valley, the Central of New Jersey, the Pennsylvania, and the Staten Island Rapid Transit railroads (Map: New Jersey, D 2). It has a fine harbor, with transportation facilities by water, and controls important shipping interests, particularly in coal. The manufactures, which are extensive, include terra cotta, bricks, chemicals, oil, cork, copper, iron, steel, and lumber, the first two named being developed from the valuable deposits of fire clay found in the vicinity. There are also two large smelting and refining plants and important shipbuilding interests. The city hall park and the bridge of the New Jersey Central Railroad are among the features of Perth Amboy. The government is administered, under a charter of 1871, by a mayor, elected every two years, and a council which has powers of election and confirmation in important administrative offices. The water-works are owned and operated by the municipality. Population, in 1890, 9512; in 1900, 17,699.

Perth Amboy was settled in 1683, and was expected soon to outstrip its neighbors and become 'the London of America.' It was named Perth, after James, Earl of Perth, but 'Amboy,' the original Indian name for the place, was soon added. It was the capital of the province from 1684 almost continuously up to the time of the Revolution. William Franklin, the last royal Governor, was captured here in 1776. Perth Amboy was incorporated as a city in 1784. Consult Whitehead, *Contributions to the Early History of Perth Amboy* (New York, 1856).

PERTHES, pâr'tâs, Friedrich Christoph (1772-1843). A German publisher and patriot. He was born at Rudolstadt. In his fifteenth year he was apprenticed to a Leipzig bookseller, with whom he remained six years. In 1793 he was employed by Hoffman, the Hamburg bookseller, and in 1796 started business on his own account, and developed an important publishing business. The iron rule of the French in Northern Germany, and the prohibition of intercourse with England, nearly ruined trade, yet Perthes found ways and means to extend his business. He endeavored to enlist the intellect of Germany on the side of patriotism, and in 1810 started the *National Museum.* Its success was far beyond Perthes's expectations, and encouraged him to continue his patriotic activity, till Hamburg was formally incorporated with the French Empire. He subsequently took a prominent part in the movement that forced the French garrison to evacuate Hamburg, March 12, 1813; and on its reoccupation by the French, he was one of the ten citizens who were specially excepted from pardon. In 1822 Perthes removed to Gotha, where he devoted himself to the publication of historical and theo-

logical works. He was the prime mover in the organization of the German book trade and in the foundation of a museum connected therewith. His correspondence with literary, political, and theological notables is extremely interesting, and throws light upon the inner life of Germany early in the nineteenth century. Consult the biography (12th ed., 1853), by his second son, Clemens Theodor Perthes.

PERTHITE. A red flesh-colored feldspar, consisting of interlaminated orthoclase and albite, that is found in Perth, Canada. It often affords bright aventurine reflections, and consequently is in some demand as a gem.

PERTH'SHIRE. An east midland county of Scotland, bounded north by Inverness and Aberdeen, east by Forfar, Fife, and Kinross, south by Sterling and Clackmannan, and west by Argyll and Dumbarton (Map: Scotland, D 3). Area, 2528 square miles. It is divided into highland and lowland districts, the former occupying the larger surface. The Grampian Mountains here reach altitudes of 3843 and 4000 feet respectively in Ben More and Ben Lawers. The lakes are numerous and include Locks Tay, Erieht, Katrine, and Aehray. The principal river is the Tay. The climate is comparatively mild and healthful. Old red sandstone, granite, and slate abound; in the lowland districts the soil is composed mostly of a rich loam, in which crops of all kinds are brought to perfection; only about one-fifth of the total area, however, is under cultivation. The highland districts are chiefly devoted to sheep pasturage and extensive deer forests. Stock-raising is largely carried on. The chief industries are the manufacture of textiles, bleaching, and dyeing. Capital, Perth. Population of county, in 1891, 122,185; in 1901, 123,260. Consult Drummond, *Perthshire in Bygone Days* (London, 1879).

PERTINAX, Publius Helvius, Emperor of Rome. He was born, according to Dio Cassius, at Alba-Pompeia, a Roman colony of Liguria, A.D. 126. He received a good education, and, entering the military service, rose through the various grades till he obtained the command of the First Legion, at the head of which he signalized himself in Rhætia and Noricum against the native tribes. In 179, or, according to other authorities, in 172, he was chosen consul, aided in repressing the revolt of Avitus in Syria, and was Governor successively of the provinces of Mœsia, Dacia, and Syria. He was sent by the Emperor Commodus to take the command of the turbulent legions in Britain, and these troops, against his will, proclaimed him Emperor; on which he solicited a recall, and was appointed proconsul of Africa, prefect of Rome, and consul (a second time) in 192. On the death of Commodus, his assassins almost forced Pertinax to accept the purple, which with great hesitation he did (January 1, 193), but in spite of his promise of a large donation, he was unable to gain over the Prætorian Guard. His accession was, however, hailed with delight by the Senate and people, who were rejoiced to have, as ruler, an able captain, instead of a ferocious debauchee; and Pertinax, encouraged by this favorable reception, announced his intention of carrying out an extensive series of reforms, having reference chiefly to the army, in which he hoped to reëstablish the ancient Roman discipline. Unfortunately, he was attacked by a band of the rebellious prætorians, about three months after his accession, and, disdaining to flee, was slain (March 28, 193). His head was carried about the streets of Rome in triumph.

PERTURBATIONS (Lat. *perturbatio*, confusion, from *perturbare*, to confuse, from *per*, through + *turbare*, to disturb, from *turba*, throng, tumult). In astronomy, a term used to describe disturbances in the orbital motion of the planets or other celestial bodies. The simplest kind of motion imaginable under the law of gravitation would be that of a small material particle revolving about a larger central attracting body. If this particle is so small that its mass may be neglected altogether, as being inappreciable in comparison with that of the central body, then the particle will describe an elliptic orbit having the larger body in one of its foci. If, however, both bodies have masses so large that neither is negligible, then each body will describe an elliptic orbit having the common centre of gravity of the two bodies in the common focus, and its distance from either body will be inversely proportional to that body's mass. Thus the larger body will describe proportionally the smaller orbit. The problem of determining mathematically all the circumstances of motion in such a system is called the 'problem of two bodies,' and its complete solution is possible. When the number of bodies in a system is increased to three, we have the famous 'problem of three bodies,' whose complete mathematical solution has never been made. It is not even certain whether our inability to solve this problem completely is due to the lack of sufficient power in the known methods of mathematical analysis, or to the fact that the problem is actually insoluble. Fortunately, astronomers have been able to obtain an approximate solution of the problem as it actually exists in the solar system, and this approximate solution is sufficiently exact for all practical purposes of predicting planetary phenomena. This solution is made by taking advantage of the fact that all the planets in the solar system are very small in comparison with the central body, the sun. The effect of this is to make such planet describe an orbit very nearly the same as the elliptic curve in which it would move if that planet and the sun were the only bodies in the system. Consequently, astronomers can predict planetary phenomena on the assumption that the orbit is a true ellipse, and then calculate the small disturbances or perturbations produced by the gravitational attraction of the other planets in the system. The continuing action of perturbative attraction may in time produce certain changes in the size, shape, and position of an orbit. Suppose, for instance, that in the case of a given planet perturbative action should suddenly cease. Then the planet would go on from that moment in a true elliptic orbit which would never undergo further change. But the ellipse would not be the same ellipse if the perturbative action were to stop to-day as it would have been if that cessation of action had occurred ten thousand years ago. For in that long interval the size, shape and position of the orbit would have been changed appreciably. It follows from these considerations that we may consider perturbative action, if we choose, from the following point of view: We may regard

each planet as traveling for the moment in a certain elliptic orbit, and consider the perturbations as disturbing the orbit instead of the planet itself. Having then deduced from observation the elements (q.v.) of the orbit at a given epoch, we can calculate the changes of the orbit in another epoch, and thus predict the actual motion of the planet for any future time.

The principal planetary perturbations are of several kinds: some change a planet's position on the sky alternately forward and backward every few years (*periodic perturbations*); others require a longer cycle to act forward and backward (*long inequalities*); and lastly there are the *secular inequalities*, whose effects are so slow that hundreds of thousands of years are included in their cyclic action. The planetary periodic perturbations may displace the planets as seen from the sun by 15″ in the case of Mercury, 30″ for Venus, 60″ for the earth, and 120″ for Mars. The most important 'long inequality' is that existing between Jupiter and Saturn. It may displace the former planet 28′ and the latter as much as 48′. The long-period secular inequalities do not alter either the mean distances of the planets from the sun or their periods of revolution. But the nodes (q.v.) and perihelia (q.v.) of the orbits move continuously. The perihelia of all the planets except Venus are gradually increasing their celestial longitudes, and all the nodes are moving in the opposite direction on the ecliptic. At the same time, the inclinations of the planetary orbits to the ecliptic plane are oscillating through narrow limits in very long periods of time and the eccentricities are similarly affected. But, on the whole, the mathematical researches so far made indicate that the continued effect of gravitational perturbative action will not end in the disruption of our solar system. But its permanent existence might be jeopardied by other than gravitational forces, or by forces operating from outside the system. In the case of the moon, perturbations are more complex and larger than they are in the planetary orbits. The moon is so near us that the slightest error in her predicted position is observed with ease and certainty; and therefore her motion offers a much severer test to mathematical calculations than do the planetary phenomena. (See Moon.) Consult Tisserand, *Traité de mécanique céleste* (Paris, 1889-1894).

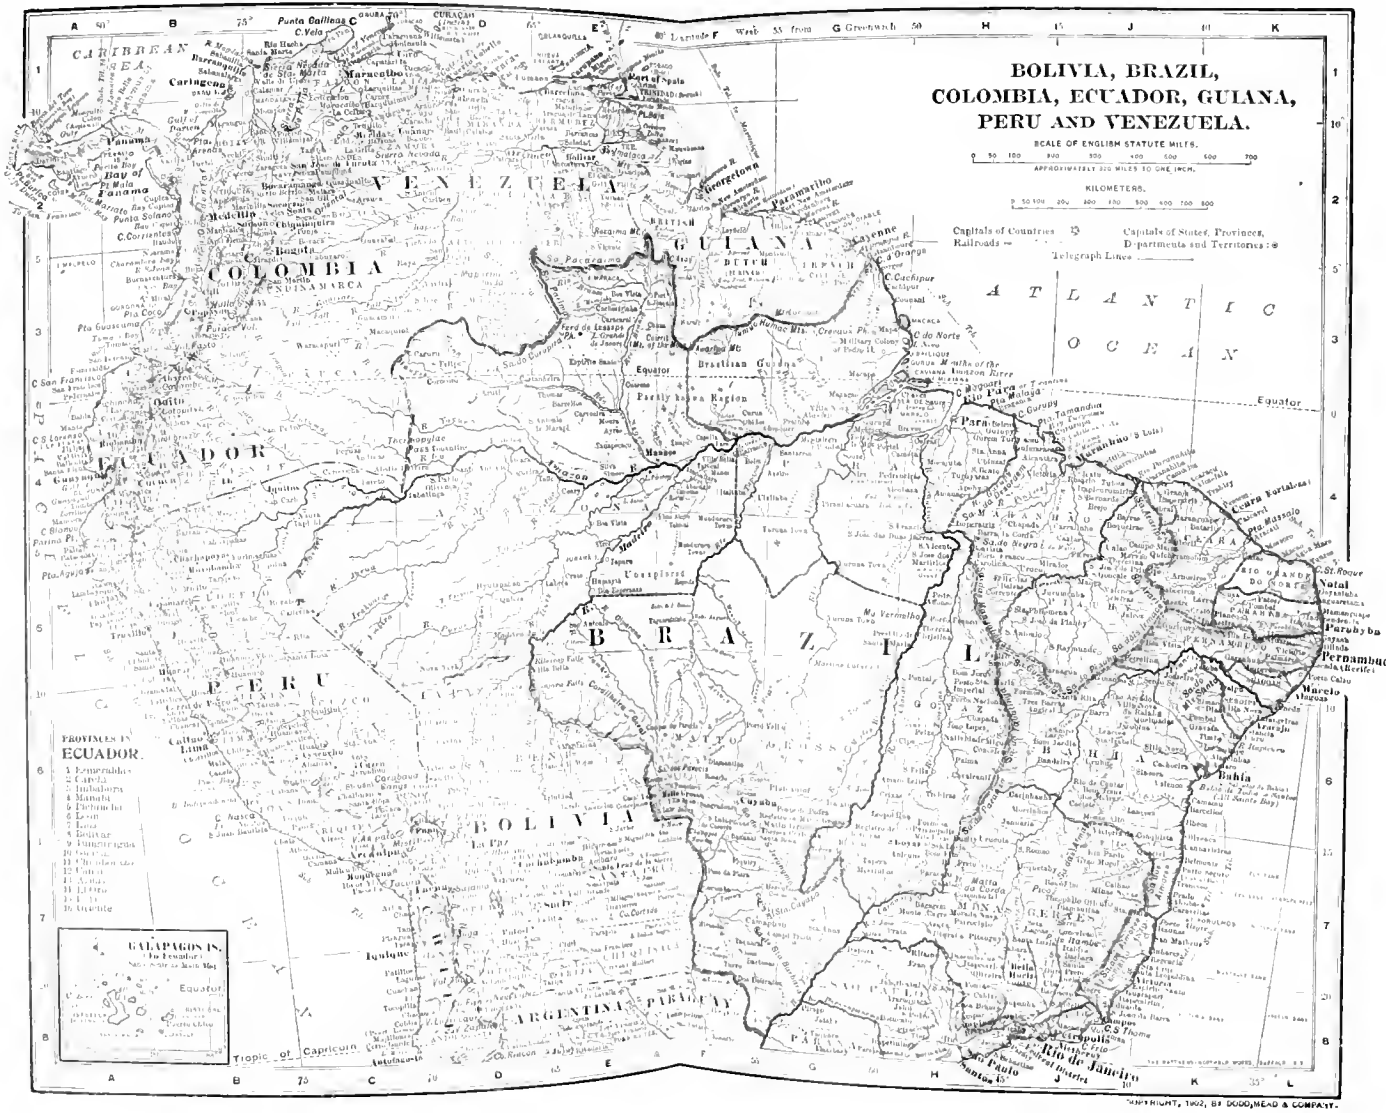
PERTUSSIS. See Whooping Cough.

PERTY, pĕr'tē, Joseph Anton Maximilian (1804-84). A German zoölogist and philosophical writer; born at Ohrban, in Middle Franconia. He studied medicine and natural history at Landshut and Munich; in 1833 became a professor in the University of Bern; and subsequently was made rector. His principal works are: *Allgemeine Naturgeschichte als philosophische und Humanitätswissenschaft* (1837-44); *Die mystischen Erscheinungen in der menschlichen Natur* (2d ed. 1872); *Ueber das Seelenleben der Tiere* (2d ed. 1875); *Blicke in das verborgene Leben des Menschengeistes* (1867); and *Erinnerungen aus dem Leben eines Natur- und Seelenforschers des 19. Jahrhunderts* (1879).

PERTZ, pĕrts, Georg Heinrich (1795-1876). A German historian. He was born at Hanover, studied at Göttingen, and at twenty-four published an authoritative *Geschichte der Merowingischen Hausmeier* (1819). Four years afterwards Pertz was appointed secretary of the royal archives of Hanover and began his important research in mediæval German history as editor of the *Monumenta Germaniæ Historica*. The materials for the Carolingian period were edited personally by Pertz, and an account of his travels and preliminary research was published in the *Archiv der Gesellschaft für ältere deutsche Geschichtskunde* (1824 et seq.). He resigned his post as editor in 1874. Pertz had become librarian and keeper of the Hanoverian archives in 1827, librarian in Berlin in 1842, and had written biographies of Stein (1849-54), and of Count von Gneisenau (1864-69). With Grotefend he edited Leibnitz's works (1843-47).

PERU' (corrupted from *Biru*, name of a chief of the early sixteenth century, who ruled a small territory of South America near the Isthmus of Darien). One of the four countries of South America bordering on the Pacific Ocean. It is bounded on the north by Ecuador, on the east by Brazil and Bolivia, on the south by Bolivia and Chile, and on the west by the Pacific Ocean. Its frontiers on the north, east, and south cannot be exactly defined throughout their whole extent, on account of boundary disputes with Ecuador, Bolivia, and Chile still pending (1903). The coast line, however, is not affected by these disputes except for a comparatively short distance in the extreme south. In 1880 Peru claimed an area of 504,000 square miles, but its claims, according to the Lima Geographical Society, now embrace nearly 700,000 square miles. According to the last census taken (1876) the area was 463,747 square miles. Probably a near approximation to the area is 440,000 square miles actually under the present control of Peru. The length of the coast line conceded to belong to Peru is about 1100 miles, not reckoning sinuosities.

Topography. Extending north and south through Peru are three well-marked topographic divisions: the Coast Desert, the region of the Andes, and the Montaña or tropical forested plain east of the Cordilleras, and included in the basin of the Amazon. The *Zona seca* or dry zone extends along the Pacific coast from 3° S. latitude (Southern Ecuador) through Peru to 22° S. latitude in Northern Chile. Most of this sandy desert is only 20 miles in width, but in the north it is 120 miles wide. It gradually rises from the Pacific to nearly 1000 feet, where it merges with the foothills of the Andes. It is nearly as destitute of vegetation as the African Sahara, except that it is crossed at intervals by rivers, some of them rising among the snow tops of the Central Andes. The banks and valleys of these roughly parallel streams are covered with perpetual vegetation, ribbons of green among the desert waste. Here are many estates and plantations. The desert is whitish in color, owing to the large admixture of marine shells. On the sea margin steep cliffs generally rise, and the waste behind them is slightly undulating, with ridges of considerable height rising here and there. The surface is hard, excepting near the coast, where drifting sea sands are whirled aloft by the winds in clouds of dust. The coast is fairly supplied with harbors well sheltered from the sea; but at many small ports the ships of the coasting trade roll uncomfortably in open roadsteads. The bays of Payta, Sechura, Chimbote,



Callao, Samanco, and Norato are secure, land-locked havens, where the largest vessels may find shelter.

The region of the Andes is about 250 miles in width. It contains enormous chains of mountains, between which are elevated plains and tablelands, warm and fertile ravines and valleys. The mountain system consists of three Cordilleras extending from northwest to southeast, more or less parallel with the line of the coast. The two western chains, for long distances comparatively near each other, are identical in origin and have been separated by denudations in the course of many ages. On these maritime and central Cordilleras are the volcanoes and many thermal springs. Some peaks of the maritime range rise to a height of 15,000 feet. The Sierra, a name that is not applied to any particular cordillera in Peru, designates the region between the maritime and central ranges, rising from 4000 feet, where it abuts on the western, to 10,000 feet at the central mountains. This region, from 50 to 150 miles wide, is a high, broken plain, corresponding to the temperate zone of Mexico, and is best adapted for settlement by whites of the temperate zones. The central range, with culminating peaks 19,000 feet above the sea, is for the most part a distinct water-parting between the Atlantic and Pacific drainage systems, though a few Pacific streams rise to the east of this line of summits. Between the central range and the Eastern Cordillera is the Puna (signifying hard breathing), a broken plain rising from 9000 feet at its western edge to 14,000 feet at the edge of the great Eastern Cordillera of the Andes, where several of the grandest mountains of the continent are found, some of them overlooking the northern plain of Bolivia, rising 20,000 feet. On the Puna rise a number of the great southern headwaters of the Amazon. The Peruvian Andes increase in height from north to south and from west to east.

The eastern part of Peru drops steeply from the cordilleras to the plain of the Upper Amazon, called the Montaña, 800 miles in length, covered with subtropical forests, where it joins the mountains, and with dense tropical vegetation on the plain, which is cut by the eastern frontier. The Montaña is very rich in rubber and agricultural resources, with abundant navigation, and promises to be one of the most prosperous parts of Peru, though it has yet reached only the early stages of development.

Hydrography. The dry west and the rainy east of Peru naturally produce a striking contrast between the hydrographic aspects of the western and eastern slopes of the country. Only feeble streams flow to the Pacific, and most of them are lost in the desert or their waters are wholly diverted to nourish the plantations. None of them flows perennially to the Pacific excepting the Santa, which rises, not on the western slopes of the mountains, like most of the coast rivers, but in a long valley between the maritime and central ranges. During the flood the Santa discharges such an enormous quantity of water that it is difficult to cross. Most of the coast rivers are quite short, and their great value is derived wholly from the facilities they afford, by means of irrigation, for turning belts of the desert into the most fertile of lands. The more important among them, from north to south, are the Chira, the Piura, the Santa, the Rimac, which created the fertile plain on which Lima stands, and the Rio Grande.

The Amazonian affluents of the eastern slope, on the other hand, constantly increase in volume with distance from their sources. The rivulets among them carry more water than most of the Pacific streams. The upper parts of these rivers are interrupted by cascades and rapids, and thus the economic periphery of Eastern Peru is largely determined by the line joining the heads of navigation on these many rivers. All the very numerous rivers of the eastern slope of Peru are included in the Amazon basin, and belong to one or another of the three secondary basins of the Marañón, the Huallaga, and the Ucayale, which are entirely in Peruvian territory, besides a few tributaries of the Purus and Madeira. The Marañón is usually regarded as the main upper branch of the Amazon, not because it carries so much water as the Ucayale, but because it prolongs farthest toward the Pacific the longitudinal axis of the Amazon. Ocean steamers now regularly ascend the Amazon and Marañón to Iquitos, Peru, 3000 miles from the Atlantic, and light-draught steamers prolong navigation for 825 miles up the Ucalaye, Pachitea, and Pichis rivers. There are no important lakes excepting Titicaca (q.v.), which lies partly in Bolivia; it is 12,500 feet above sea-level, and affords navigation between Peruvian and Bolivian ports on its shores.

Climate. The chief determining influences on the climate are the trade winds and the great differences in elevation. The country is more temperate than might be expected from its position in the tropics. The trade winds coming west from the Atlantic deluge the eastern mountains, drop cold rain and snow upon the Puna, give a smaller supply of water to the central range, and moisten the plain of the Sierra to some extent. So little water is left for the maritime range that it is included with the coastal desert in the dry belt. These facts explain the aridity of the west slope of Peru. Once in seven or eight years a marvelous change comes over the face of this desert. Sufficient rain comes over the mountains to bring life out of the parched surface: grass and flowering plants appear, attracting thousands of cattle and goats from the irrigated valleys to the new pasturage, which withers again in a few weeks. Only about 1½ inches of rain fall in Lima in a year. The mean annual temperature of the coast provinces is 68° F. In the hottest months, January and February, the mean temperature is between 82° and 86°. The dry heat is not oppressive; and after 11 A.M., when the torrid sun has rarefied the atmosphere over the desert, sea air comes rushing to this area of low pressure, all life is refreshed by the breeze, and often a little rain is scattered over the maritime range. In the evening, when the surface of the desert grows cool, the wind sets to sea again, bringing cool breezes from the mountains. Conditions are nowhere unhealthful excepting in the low, hot plains of the north and east. The whole mountain region lying between 3000 and 9000 feet above the sea has a temperate and healthful climate. Thus in nearly all parts of Peru the climate is exceptional.

Flora. Varying with the climate, the flora of Peru is represented on the dry coast only by a few gray herbs and in the depressions by the Prosopis, a low tree of scraggy growth, and two

stigas, the Capparis and a variety of Apocynum. The western slopes of the maritime range, exposed to fogs and occasional rains, have sufficient vegetation to give them a green aspect mixed with yellow due to the abundance of yellow marguerites. The high plateaus among the mountains have a great variety of species, among which resinous and other herbs and the gigantic cactus are especially abundant, and several varieties of forest trees are found. The flora of every zone is represented among the mountains, from the tropical in the deep gorges to the Arctic approaching the snow line. The potato thrives and the llama, vicuña, and sheep feed on the grasses of the uplands. The most valuable plants, economically, are the quinine-yielding cinchona, the coca plant, from which cocaine is derived, the Siphocampylus, a plant 50 feet high, from which Peruvian rubber is extracted, and the sarsaparilla.

Fauna. The headlands of the coast and the neighboring islands are the home of myriads of sea birds, whence came the immense deposits of guano that were long a great source of Peruvian wealth. Among them are the guano bird (*Sula variegata*), a large gull (*Larus modestus*), a tern (*Sterna inca*), and several cormorants. Sea-lions (*Otaria forsteri*) are common on the promontories and islands. The domesticated llama and alpaca and the wild vicuña belong especially to the mountain regions; among the other animals of the highlands are the tarnco, a deer, the viscacha, a large rodent, the atoc, a species of fox, the puma, and two species of bear. The largest bird is the condor; another bird of the vulture family whose black and white wing feather was used by the Incas in their headdress is the coraquenque. Woodpeckers, a species of partridge, geese, a plover, two kinds of ibis, gulls, water hens, finches, and parrots are also found. Nearly all the characteristic animals of tropical South America are found in the Montaña, including monkeys, the tiger cat, jaguar, tapir, peccary, tortoise, alligator, manatee, snakes, and vipers.

Geology and Mineral Resources. Sections of the desert zone, exposed along the coast and valleys for several hundred feet, reveal nearly horizontal layers of calcareous sandstone above strata of pudding stone and shell marl, beneath which are beds of argillaceous shale, considerably tilted and often of immense thickness. The ridges found on the coast plain are of granite or syenite. The Maritime and Central Cordilleras consist chiefly of crystalline and volcanic rocks on each side of which are sedimentary strata, principally of Jurassic age. The Eastern Cordillera is in great part of Silurian formation, with talcose and clay slates, many quartz veins, and intrusions of granite rocks. The igneous cones of Peru are found in the southern section of the maritime and central ranges, about 1200 miles south of those in Ecuador. None of them has been in eruption in recent times. Sara-Sara, Achatayhua, Coro Puna, Ampato (all over 13,000 feet), Chachani (19,820 feet), and Misti (about 20,000 feet) are quiescent and snow-clad. Misti, a magnificent cone, near whose base stands the city of Arequipa, appears to be the focus from which some of the earthquakes that afflict Peru have been propagated. South of Misti is the elongated crest of the volcano of Omate, in the seventeenth century the most active of the Peruvian volcanoes. Farther south is Tutupaca (18,960 feet), which as late as 1862 was still ejecting vapors by which a little sulphur was deposited. The frequent and severe earthquakes are most destructive in the neighborhood of these southern volcanoes. In 1746 Callao and in 1868 Arequipa were destroyed by earthquakes. The shocks of 1877 were equally severe, and all the southern ports were overwhelmed by earthquake waves.

Peru is a vast storehouse of mineral wealth, though it long ago lost the first rank as a mining country, and is now surpassed even by Bolivia and Chile. The Eastern Cordillera contains gold in the quartz veins of the Silurian strata, but the annual yield is small because the richest mines occur in the most unhealthful and remote parts of the Montaña, where miners dislike to go, and transportation is very difficult. The Central and Maritime Cordilleras are poor in gold, but rich in silver, which occurs nearly always with antimony, copper, and lead. Copper is found in greatest abundance in the coast lands, where also are important areas of salt, borax, and petroleum (in Piura). Anthracite and bituminous coal are reported in the province of Hualgayoc and are known to exist in the Huamachuco and other districts. But silver remains the chief mineral product. The greatest centre of the industry is at Cerro de Pasco, which produced $475,000,000 of silver between 1630 and 1849, and has yielded an average of about 1,200,000 ounces a year for the past ten years, dropping, however, to 1,000,000 ounces in 1901, owing to the inundation of some of the chief mines, which will be drained by a tunnel. Other important silver-mining centres are those around Puno, and at Caylloma, Castrovireina, and Recuay. United States and British companies are largely interested in the mining industry, and the number of mines increased from 1456 in 1886 to 3475 in 1897. In 1900 there were 5178 mining claims, including silver, gold, copper, quicksilver, lead, zinc, coal, sulphur, salt, and petroleum. Many of these claims are unworked.

Agriculture. The chief crops of the fertile coast valleys are sugar, cotton, and coffee. In 1903, 370,650 acres of these irrigated lands were in sugar-cane, which is grown to perfection, 12.5 tons of cane yielding a ton of sugar, the great export crop, and the basis of agricultural prosperity. The unoccupied land capable of producing sugar is measurable only by the possibilities of irrigation. Cotton is indigenous, and that grown in the northern provinces is distinctive (tree cotton), the plant often reaching a height of 20 feet and producing for 7 to 10 years, the fibre ranging in color from pure white to dark brown. This cotton is especially valued for mixing with fine wool, to which it adds strength, lustre, and protection against shrinkage. Its value is greater than that of any other cotton excepting American sea island. The ordinary staple grown in the coast valleys farther south is adapted for spinning fine yarns. Extensive irrigation works both north and south are now being developed to enlarge the area of cotton culture, and the product is steadily increasing. Rice and tobacco are important crops, and there are several large establishments for the preparation of rice for market. Maize and alfalfa (lucerne), vegetables, and fruits of all kinds are cultivated in every valley. Grape culture is increasing, and the production of wine is impor-

tant. Olives are grown in the south, and there are many profitable grazing farms in the coast valleys. In the valleys and to some extent on the plateaus of the Andean region wheat and barley ripen, the potato is a very successful crop, and the cultivation of coffee is a growing industry. The cultivation of the cacao-tree is especially successful in the valley of the Pérené River in the Montaña, where 200,000 trees were recently added to the plantations. In 1901, 107 tons of cacao were exported. Over 1500 tons of rubber are annually shipped from the Montaña, whose other chief products are cinchona, dyes, and medicinal substances, all the exports going down the Amazon from Iquitos. The coca-tree thrives best near the Pacific, in the Department of La Libertad, where in 1901 there were 2,700,000 trees, the exports being 610 tons of coca and 10.69 tons of cocaine.

MANUFACTURES. The manufacturing industries have as yet little importance, though some progress is being made. Five cotton factories operate 1400 looms, but they supply only a small part of the cotton cloths required. Beer, boots and shoes, wine, clothing, furniture, watches, soap, lard, saddlery, olive oil, and cottonseed-oil cake are among the other products, Callao and its environs being the chief centre of production. The Indians of the north make fine straw hats, which enter the trade as Panama hats, though the name is properly applied only to the product of Ecuadorian natives. Indians on the mountain plateaus make coarse woolen fabrics and earthenware for local consumption; and a few coast towns produce filigree and other fancy articles. The quantity of petroleum refined is not large. Owing to the small variety and quantity of home manufactures, it is necessary to import a great deal of machinery and wares of all kinds.

COMMERCE. Peru's business relations with foreign countries have been steadily increasing in recent years. The following table shows the progressive growth in the value of international commerce for six years:

	1896	1897	1898	1899	1900	1901
Exportation	$6,113,678	$6,760,428	$7,265,945	$7,374,218	$10,795,198	$10,316,109
Importation	4,201,234	3,870,874	4,611,540	4,496,486	5,561,160	6,619,737
Total	$10,314,912	$10,631,302	$11,877,485	$11,870,704	$16,356,358	$16,935,846

The following table shows the progressive increase in metric tons in the exports of the ten principal products of Peru for the same period:

ARTICLE	1896	1897	1898	1899	1900	1901
Cotton	4,718	5,586	6,712	5,876	7,246	8,011
Rice	2,804	4,222	4,276	2,874	4,260	4,164
Sugar	71,735	105,463	105,713	103,706	114,222	114,637
Cocoa		12	62	54	99.3	107
Coffee	714	1,240	1,245	1,215	1,154	946
Coca leaves		497	430	312	566	610
Cocaine		4.2	4.35	4.5	7.75	10.6
Leather	1,332	1,710	2,127	2,062	2,286	2,251
Wool	2,544	3,770	3,189	3,434	3,534	3,856
Minerals	12,000	15,000	17,225	23,158	39,405	46,885

In the sugar trade, Peru has the great advantage that the fields are cheaply irrigated and the absence of rain permits grinding for three-fourths of the year. Raw sugar is therefore produced at small cost. About five-sixths of the crop is exported, Great Britain, the United States, and Chile being the largest buyers. The distinctive qualities of Peruvian cotton create a demand for it in the leading woolen centres of this country and Europe. Coffee exports are not expanding, because most of the plantations are on the Andes slopes and transportation by mule train to the railroads is very expensive.

The principal imports and exports in 1900, in dollars, were:

IMPORTS	1900
Cottons	$1,806,285
Woolens	725,680
Other tissues	332,545
Furniture, etc	845,810
Small wares, etc.	5,884,075
Provisions, etc	1,264,515
Wines, etc	227,920
Drugs, etc	485,770

EXPORTS	1900
Ores	$8,475,275
Sugar	7,279,210
Wool	1,483,365
Cotton	1,630,370
Coffee	327,155
Borax	283,185
Hides	542,790
Rice	319,515
Cocaine	580,890

The distribution of trade to the leading countries in 1900 was:

FROM OR TO	Imports	Exports
United Kingdom	$5,405,725	$10,446,340
Germany	1,802,995	2,579,965
United States	1,487,180	4,774,480
France	781,745	702,340
Chile	457,066	3,052,600

The trade with the United States for five years was as follows: Exports from Peru in 1898, $714,247; 1899, $1,496,978; 1900, $4,774,480; 1901, $3,656,180; 1902, $3,269,411; and imports into Peru in 1898, $1,302,697; 1899, $1,325,650; 1900, $1,487,180; 1901, $3,126,934; 1902, $2,558,995.

The chief articles which Peru sold to the United States in the fiscal year 1902 were: Raw sugar (including some molasses), $2,126,686; cotton, $592,509; gold bars and concentrates, $469,772; goat skins, $265,798; coca leaves, $175,552; straw hats, $65,385; sulphide of silver, $52,745; silver ore, $36,595; rubber, $36,644; alpaca wool, $21,728; guano, $8,750. The chief

principal imports from the United States were hardware, machinery, breadstuffs, and provisions.

Transportation and Communications. Foreign vessels call at nearly every port, but most of the international trade is conducted through the port of Callao. The vessels of over 50 tons entering that port in 1901 numbered 531, of 755,461 tons; the clearances were 537 vessels, of 753,334 tons. There entered also 959 vessels under 50 tons, of 12,697 tons. About one-half of the tonnage of foreign vessels was British. The steamships of the Pacific Steam Navigation Company, on the route between Chile and San Francisco, call at nearly all the Peruvian ports. Very little freight is carried in domestic bottoms, the merchant marine of the country in 1902 consisting of only 1 steamer of 19 tons, 29 sailing vessels of 50 tons, and 86 under 50 tons, the aggregate tonnage being 10,629 tons.

Good wagon roads and bridges are among Peru's greatest needs. Western Peru is still almost isolated from the Montaña because the road on which a vast sum has been spent to connect Oroya, the terminus of the Central Railroad with the Pichis River, the head of navigation leading to Iquitos, is not yet in a satisfactory condition. Freight between Oroya and the great mining centre of Cerro de Pasco, 66 miles, is still carried by llamas, horses, and mules.

Peru in 1902 had 1035 miles of railroad in operation, of which 844 miles were worked by the Peruvian Corporation, which manages all the property turned over in liquidation of the national debt. Not only Lima, but also the larger inland towns are connected by rail with their seaports, but the country needs branches extending north and south to connect the Andean towns with the routes to the sea and with one another. Peru thus has numerous sections of a railroad system, but, owing to the lack of branches between them, the railroads are as yet wholly inadequate for the needs of the country. The greatest railroads are the line from Callao and Lima across the Maritime and Central Cordilleras to Oroya, 136 miles long, with 63 tunnels, enormous bridges, embankments, and cuttings, and a tunnel in the mountains at an altitude of 15,645 feet, the most elevated spot reached by any railroad in the world; and the railroad between the port of Mollendo and Puno on Lake Titicaca, on which there is a connection by steamers with Bolivia. The gross receipts in 1901-02 from railroads and steamers amounted to $2,508,875; the working expenses were $1,619,135. The State owns 1400 miles and the Peruvian Corporation 533 miles. There are 48 telegraph offices, and in 1901 152,808 telegrams were sent. Electric communication with the rest of the world is supplied by the cables along the coast, with stations at Payta, Callao, Lima, and Mollendo. There are 369 post-offices, which in 1900 carried 8,884,604 letters, etc.

Banking. The four commercial banks of Peru are the Bank of Peru in London (paid up capital and reserve fund, £1,058,050); the Italian Bank (paid up capital and reserve fund, $362,388); the International Bank of Peru (capital and reserve, $362,388); and the Banco Popular (capital and reserve fund, $362,388). The only savings bank had deposits in 1902 amounting to over $750,000.

Education. The municipalities maintain free public schools; elementary education is compulsory for both sexes. In 1898 there were 1544 primary schools, with 91,853 pupils. The number of teachers in the primary schools was 1991, the cost of maintaining the schools being $241,790; 2168 pupils attended the high schools maintained by the Government at the capitals of the departments. The University of San Marcos had 650 students, and faculties of jurisprudence, literature, medicine, political science, and theology. There are also universities with very small attendance at Arequipa, Cuzco, and Trujillo. A few high schools are under the direction of European teachers, and Lima has a school of mines and civil engineering and a public library.

Religion. The religion of the State is Roman Catholic, and the Constitution prohibits the public exercise of any other religion; practically, however, there is considerable toleration, and Callao, Lima, and Cuzco have Protestant churches and missionary schools. The non-Catholic population probably does not number over 30,000.

Finance. The public revenue is chiefly derived from the customs and the direct taxes levied by the departments and municipalities on rent derived from real estate. Among the other sources of revenue are the salt monopoly and the postal and telegraph services. The revenue in 1901 amounted to $7,739,307; expenditures, $7,208,626. In 1902 the expenditure was distributed as follows: Congress, $213,485; Ministry of Interior, $1,676,732; Foreign Affairs, $342,190; Justice, $724,520; Finance, $2,612,965; War and Marine, $1,926,615; Public Works, $387,260; total, $7,883,770.

Owing largely to her war with Chile, Peru was enormously in debt, her bonds being held in England to the amount of £31,579,080. Though the two loans represented by this total were secured by the guano deposits and the general resources of the country, no interest was paid on the public debt after 1876, and the arrears in 1889 amounted to £22,998,651. In 1890 Peru was released from all responsibility for the two loans, and all the railroads and rights over guano deposits, mines, and lands were ceded to the bondholders for 66 years. The Government agreed to pay $400,000 annually to the Peruvian Corporation, which was to carry on railroad building. Disputes as to the fulfillment of these conditions on both sides have not yet been settled. The internal and floating debt of Peru amount to £4,759,000, of which £2,660,645 bears interest at the rate of 1 per cent. per annum.

Money, Weights, and Measures. Peru adopted the gold standard in 1901. Both the pound sterling and the national gold coin, the libra, which is of the same standard and weight, are legal tender. Silver is legal tender up to 100 soles. The sol is worth 49 cents. Spanish standards of weight and measure are still in use, though the French metric system was established by law in 1860, and is employed in the custom houses.

Population. There has been no census since 1876, when the number of the population was given at 2,660,881, of whom about 13.8 per cent. were white, 1.9 negroes, 57.6 Indian, 24.8 mixed bloods, and 1.9 Asiatic, chiefly Chinese. The Lima Geographical Society in 1896 estimated the population at 4,609,999. The estimate is believed to be excessive. To all appearances the population is increasing very slowly, if at all. Immigration

from Europe, which is promoted by the Peruvian Corporation, is very small.

The list of departments, with their capitals and population (estimated in 1896), is given as follows:

DEPARTMENTS	Population 1896	Capitals
Piura	213,909	Piura
Cajamarca	442,412	Cajamarca
Amazonas	70,676	Chachapoyas
Loreto	100,596	Moyobamba
La Libertad	250,931	Trujillo
Ancachs	428,703	Huaraz
Lima	298,106	Lima
Callao	48,118	Callao
Huancavelica	223,796	Huancavelica
Huánuco	145,309	Huánuco
Junin	304,393	Cerro de Pasco
Ica	90,962	Ica
Ayacucho	302,469	Ayacucho
Cuzco	438,646	Cuzco
Puno	537,345	Puno
Arequipa	229,007	Arequipa
Moquegua	42,694	Moquegua
Apurimac	177,387	Abancay
Lambayeque	124,091	Lambayeque
Total	4,559,550	

GOVERNMENT. For political purposes the Republic of Peru is divided into 17 departments and 2 provinces (Callao and Moquegua), and these departments in turn are subdivided into 90 provinces. The present Constitution, based on that of the United States, was proclaimed in 1856 and revised four years later. Under it the executive power is vested in a President, who must be thirty-five years of age, and a native Peruvian, elected by direct vote for four years, and two Vice-Presidents elected for the same period. The President is ineligible for two consecutive terms. He is assisted by six responsible ministers, who hold office at his pleasure, but whose signature is necessary to validate his acts.

The legislative power is vested in a Senate of 48 members and a Chamber of Deputies of 108. The Senators, with the same age and residence qualifications as the President, are elected by departments, the number varying from one to four, according to the number of provinces in the department. The Deputies, Peruvians by birth and citizens of good standing, are elected in the proportion of one for every 30,000 inhabitants or majority fraction, though each province is entitled to one representative even if its population is less than 15,000. Senators must have an annual income of $1000 and Deputies of $500, or have a scientific profession. They are elected indirectly by provincial electoral colleges and serve six years.

The judicial power is vested in a Supreme Court of Justice, whose members are elected by Congress from names submitted by the President; superior courts in each department, whose members are appointed by the President; and judges of first instance in each province and local justices in each municipality, appointed by the judges of the superior courts. The conduct of all trials must be public. The executive and police powers of the Republic depend directly upon the President, who appoints the prefects of the various departments and the sub-prefects, who control the provinces. The districts are under Governors appointed by the prefects, and the municipalities under Lieutenant-Governors appointed by the sub-prefects. All police officials hold directly from the President. Citizenship is restricted by educational and property qualifications. The capital of the Republic is Lima.

ARMY AND NAVY. The army is to be reorganized. It numbers some 4000 men on a peace footing. There is a new military academy near Lima. The navy has four small vessels in more or less bad condition.

HISTORY. Little is clearly ascertainable regarding the early history of the Peruvian Empire, and the lists given of its early sovereigns are by no means to be trusted. Almost all we know of their early history is derived from the traditions of the people, collected by the early Spaniards. (See PERUVIAN ANTIQUITIES.) In 1453 Tupac Inca Yupanqui, the eleventh Inca, according to the list given by Garcilaso de la Vega (q.v.), greatly enlarged his widespread dominions. He led his armies southward into Chile, marched over the terrible desert of Atacama, and, penetrating as far south as the River Maule, fixed there the southern boundary of Peru. While thus engaged, his son, the young Huayna Capac (q.v.), heir to the fame as well as the throne of his father, had marched northward to the Amazon, crossed that barrier, and conquered the Kingdom of Quito. In 1475 Huayna Capac ascended the throne, and under him the Empire of the Incas attained to its greatest extent, his sway extending from the valley of the Amazon to Chile and from the shores of the Pacific to the sources of the Paraguay.

About the year 1516, and ten years before the death of Huayna Capac, the first white man had landed on the western shores of South America; but it was not till the year 1531 that Pizarro (q.v.), at the head of a small band of Spanish adventurers, actually invaded Peru. On his death-bed the great Inca had expressed a wish that the Kingdom of Quito should pass to Atahualpa (q.v.), one of his sons by a princess of Quito, and that all his other territories should fall to his legitimate son, Huascar, the heir to the crown, and who, according to the custom of the Incas, should have inherited all its dependencies. Between these two princes, quarrels, resulting in war, arose; and when Pizarro entered Peru he found the country occupied by two rival factions. Atahualpa had completely defeated the forces of his brother, had taken Huascar prisoner, and was now stationed at Caxamalca, on the eastern side of the Andes, whither, with a force of 102 foot soldiers and 62 horsemen and two small falconets or cannon, the dauntless Spanish leader, in September, 1532, set out to meet him. Shortly after the execution of Atahualpa (August, 1533) at Caxamalca the invaders set out for Cuzco. Their strength had been increased by reënforcements, and they now numbered nearly 500 men, of whom about a third were cavalry. They entered the Peruvian capital November 15, 1533, having in the course of their progress toward the city of the Incas had many sharp encounters with the Indians, in all of which their armor, artillery, and cavalry gave them the advantage. At Cuzco they obtained a vast amount of gold, the one object for which the conquest of Peru was undertaken. As at Caxamalca, the articles of gold were for the most part melted down into ingots, and divided among the band. After stripping the palaces and temples of their treasures, Pizarro placed Manco,

a son of the great Huayna Capac, on the throne of the Incas. Leaving a garrison in the capital, he then marched west to the seacoast, with the intention of building a town, from which he could the more easily repel invasion from without, and which should be the future capital of the kingdom. Choosing the banks of the river Rimac, he founded, about six miles from its mouth, the *Ciudad de los Reyes*, 'City of the Kings.' Subsequently its name was changed to Lima, the modified form of the name of the river on which it was placed. The Inca Manco succeeded in effecting his escape, and headed a formidable rising of the natives. Gathering around Cuzco in immense numbers, the natives laid siege to the city, and set it on fire. The city was relieved by the failure of provisions among the besiegers and the departure of the Peruvians for their farms. The advantages, many, though unimportant, which the Inca gained in the course of this siege, were his last triumphs. He afterwards retired to the mountains, where he soon after perished. More formidable, however, to Pizarro than any rising of the natives, was the quarrel between himself and Almagro (q.v.), a soldier of generous disposition, but of fiery temper, who, after Pizarro, held the highest rank among the conquerors. Civil war ensued in which Almagro was defeated and put to death. His followers, however, plotted revenge, and in 1541 Pizarro fell beneath their swords. The son of Almagro then proclaimed himself Governor, but was soon defeated in battle and put to death. In 1542 a council at Valladolid in Spain, called at the instigation of the ecclesiastic Las Casas, who deplored the cruelties committed on the natives, framed a code of laws, known as the 'New Laws for the Indies,' for Mexico and Peru, according to which the Indians who had been enslaved by the Spaniards were virtually declared free men. It was also enacted that the Indians were not to be forced to labor in unhealthy localities, and that whenever they were desired to work in any particular locality they were to be fairly paid. Blasco Nuñez Vela, sent from Spain to enforce the new laws, rendered himself unpopular, and was seized and sent back to Panama. He had come from Spain accompanied by an *audiencia* of four, who now undertook the government. Gonzalo Pizarro (q.v.) was induced to declare himself Captain-General of Peru and marched upon Lima. He was too powerful to withstand, and the audiencia elected him Governor as well as Captain-General of the country. Pizarro was overthrown by Pedro de la Gasca and put to death in 1548.

A series of petty quarrels and the tiresome story of the substitution of one ruling functionary for another make up a great part of the history of Peru during the next two centuries. The country became one of the four viceroyalties of Spanish America, and the Spanish authority was fully established and administered by successive viceroys. The Province of Quito was separated from Peru in 1718, and in 1788 considerable territories in the south were detached and formed into the Government of Buenos Ayres. At the outbreak of the War of Independence in South America, Spain, which had declined greatly in internal strength, was distracted by the French invasion and the dissensions of a regency; nevertheless in July, 1816, when the Viceroy Abascal turned over his office to Don Joaquin de la Pezuela, there was a Spanish army of 23,000 men in Peru and all resistance had apparently been stamped out in Chile, Upper Peru (Bolivia), Quito, and New Granada, Buenos Ayres alone maintaining her independence. Peru was the last of the Spanish South American possessions to set up the standard of independence. In August, 1820, an army under General San Martin, one of the liberators of Chile, landed at Lima, and, after a number of successes both on sea and land, in which the patriots were effectively assisted by Lord Cochrane, General Miller, and other English volunteers, the independence of the country was proclaimed at Lima, July 28, 1821. San Martin assumed the protectorate of the young Republic. By the spring of 1822 he had forced the surrender of the last large body of Spanish troops. At this juncture General Bolivar (q.v.), flushed with his successes in the north, landed at Guayaquil. San Martin, recognizing the dangers of rivalry, arranged a meeting on July 26, 1822, the details of which were never made public, but as a result of which San Martin resigned, and, a year later, retired to England. A Congress was summoned, and on February 28, 1823, Don José de la Riva Aguero was installed as the first President of Peru. Meanwhile the scattered bands of Spanish royalists had managed to collect in the south, around Cuzco, and the agents of Bolivar succeeded in persuading the Congress to depose Riva Aguero. On September 1, 1823, Bolivar landed at Callao and devoted himself to organizing an army. On February 10, 1824, he was appointed supreme dictator by the Congress. For a while the royalists under Canterac made considerable headway, occupying Callao Castle and forcing Bolivar to evacuate Lima. The two armies met on the plains of Junin, where a remarkable battle was fought in which the Peruvian cavalry turned defeat into victory by repeated charges with their lances. The Spaniards retired to Cuzco, where the Viceroy, La Serna, concentrated his forces for a final stand. On December 9th a battle was fought at Ayacucho in which the patriots, under General Sucre, were completely successful, and the Spanish officials and generals, with over three thousand soldiers, surrendered. The guerrilla fighting continued for a while in the north, where General Olañate stubbornly held out until shot by his own troops in April, 1825. In 1826 the Spaniards evacuated Callao and the war was at an end. Bolivar, on February 10, 1825, resigned the dictatorship, but was immediately reappointed, and remained in control of the Government until March, 1827, when he returned to Colombia with his soldiers. On June 4, 1827, a congress met and framed a provisional Constitution, adopted in 1828. General Lamar was elected President. Lamar promptly forced a quarrel with Bolivar, who declared war and defeated him, enforcing a money indemnity and the surrender of Guayaquil. The history of the next thirty-five years is the record of repeated changes in Government, one man after another gaining a personal ascendency, lasting a few days or years, until some rival took advantage of his mistakes to supplant him. Withal, the state of the country gradually improved, commercially, socially, and intellectually, but with few events of especial interest or importance.

In April, 1864, a Spanish squadron seized the

Chincha Islands in reparation for injuries sustained by Spanish subjects. President Pezet was unwilling to risk a war with Spain, and a treaty of peace was signed in January, 1865. The action of the President aroused bitter opposition in the country; he was declared a traitor by the Assembly, and in February a revolution broke out which ended in the overthrow of Pezet and the proclamation of Mariano Ignacio Prado as dictator (November 26, 1865). An alliance against Spain was concluded with Chile, Ecuador, and Bolivia, war being declared in January, 1866. On May 2, 1866, a Spanish fleet bombarded Callao, but was compelled to withdraw. This marked the termination of hostilities. In 1879 Peru as the ally of Bolivia became involved in war with Chile. (See BOLIVIA; CHILE.) In October, 1879, the Peruvian man-of-war *Huascar* was captured by the Chilean fleet, and on November 19th the forces of Bolivia and Peru were overwhelmed at Dolores. A Chilean army under General Baquedano captured Moquegua and Tacna, two important cities in Southern Peru, in March and May, 1880. Early in June the same general carried the almost impregnable stronghold of Arica by storm, thus gaining possession of the whole of Southern Peru. In the meantime the Chilean fleet was blockading or pillaging the Northern Peruvian seaports. The Peruvians refusing to accede to the terms for peace dictated by Chile, Baquedano organized an expedition against Lima. This expedition started in November, by water, and landed at Pisco and Curayaco, about 200 miles south of Lima. With an army 30,000 strong, the Chilean general marched on the capital, spreading devastation along the way. The Peruvians were defeated at Chorillos on January 13, 1881, and at Miraflores on January 15th, and on January 17th the Chileans made their entry into Lima. Capt. Patrick Lynch, the leader in a raid which had devastated the northern coast towns, was appointed Chilean commandant of the town. After the fall of Lima desultory fighting continued until a treaty of peace was concluded, October 20, 1883. Peru ceded to Chile the District of Tarapacá and the Territories of Tacna and Arica for a term of ten years; the people of these territories to decide by popular vote whether they wished to return to Peru or to remain under Chilean rule. This term was further extended, Chile apparently distrusting the result of the plebiscite, and the territory has become practically Chilean. The war left Peru in a shattered and bankrupt condition, from which it has very slowly recovered. Boundary disputes, especially with Chile, have arisen periodically to threaten the peace relations.

PERU'. A city in Lasalle County, Ill., about 60 miles north-northeast of Peoria; at the head of navigation on the Illinois River, on the Illinois and Michigan Canal, and on the Chicago, Rock Island and Pacific Railroad (Map: Illinois, C 2). Picturesquely situated, it has a public square and public parks, and is the seat of Saint Bede College (Roman Catholic), opened in 1891. Among the prominent buildings are Turner Hall and the Masonic Building. There are four bridges here, including a fine railroad bridge. Peru is the centre of valuable bituminous coal fields and of extensive deposits of cement rock and white sand rock. Its industrial establishments include large zinc-rolling mills and furnaces, a foundry and machine shop, scale works, plow and wheel works, clock works, breweries, grain elevators, nickeloid works, a planing mill, and fertilizer works. The government is administered under a charter of 1890, by a mayor elected every two years, and a council. The water-works and the electric light plant are owned and operated by the municipality. Peru was first settled in 1827 and laid out in 1834. In 1852 it was chartered as a city. For the archæologist, the vicinity presents much interest, as there are relics of the Mound Builders. Population, in 1890, 5550; in 1900, 6863.

PERU. A city and the county-seat of Miami County, Ind., 75 miles north of Indianapolis; on the Wabash River, and on the Wabash, the Lake Erie and Western, and the Cincinnati, Richmond and Muncie railroads (Map: Indiana, C 2). Five bridges span the river at this point. The city has a public library, the Wabash Railroad Hospital, a sanatorium, and Boyd Park. It derives considerable trade from the tributary country, which is largely agricultural. There are railroad shops of the Erie, and of the Cincinnati, Richmond and Muncie, carbon works, woolen mills, basket factory, bagging mills, glass works, steel works, a cabinet factory, wagon shops, a candy factory, etc. Peru, incorporated in 1848, is now governed under a charter of 1868 which provides for a mayor, elected biennially, and a council. There are municipal water-works and a municipal electric light plant. Population, in 1890, 7028; in 1900, 8463.

PERU BALSAM. See BALSAM.

PERUGIA, pā-rōō'jä. The capital of the Province of Perugia, Italy, situated on picturesque hills between the Tiber and Lago Trasimeno, at an altitude of 1700 feet above the sea, 103 miles by rail southeast of Florence, and the same distance north of Rome (Map: Italy, G 4). Its situation is beautiful, offering delightful views of the Umbrian and Foligno valleys, and of the Tiber and the Apennines. Its mediæval appearance also is attractive and interesting. It has many striking edifices dating from its glorious days at the beginning of the Renaissance period, and numerous art treasures, but is not nearly so much frequented as Orvieto and Siena, with their famous cathedrals.

Perugia is irregularly laid out. Many of its substructures belong to the ancient Etruscan town. It possesses ample squares and pleasant grounds. The unfinished Gothic Cathedral of San Lorenzo is not very striking, although of the Renaissance period. The most valuable of its varied contents is Signorelli's "Madonna with John the Baptist." Its library possesses ancient and costly manuscripts. The Oratorio di San Bernadino has a multi-colored early Renaissance façade. The San Domenico is a fine Gothic church which has been attributed to Giovanni Pisano. It was rebuilt in 1614, and contains the elaborate and celebrated monument to Benedict XI. The Basilica San Pietro de' Cassinensi in the vicinity is also notable. It was constructed about 1000. It contains noteworthy pictures by Perugino, Caravaggio, and others, and has rich choir stalls in walnut. The notable old secular edifices of Perugia include the fine Collegio del Cambio, with its celebrated mural paintings of the Chief Virtues by Perugino —his finest fresco—and other artistic features, all in the best Renaissance. The immense Palazzo del Municipio, dating from 1281, is in Italian Gothic with two façades. It has been latterly restored, and is elaborately embellished with ancient sculptures, etc. Under its roof are the Vannucci picture gallery (municipal), a valuable collection of ancient Umbrian works taken from suppressed religious institutions, and the public library, with over 30,000 volumes and some rare mediæval manuscripts.

The finest section of the picture gallery is the Sala del Pinturicchio, with examples by Perugino and Pinturicchio. The College of San Severo is a notable ancient building, formerly a cloister. Here Raphael, who had been a pupil of Perugino, painted his first fresco in 1505. It is now in a spoiled condition. Among the attractive modern buildings are the arcaded Prefettura. In the centre of the modern city is a fine bronze equestrian statue of Victor Emmanuel II. Perugia has also a bronze statue of Julius III., a monument to Garibaldi, and a monument to the soldiers who fell for freedom in 1859. There are, besides, the beautiful Maggiore fountain, dating from the close of the thirteenth century and bearing reliefs by Nicola and Giovanni Pisano; the striking Roman Arch of Augustus, constructed in the third century of our era, and still one of the gateways of the city; and the house where Perugino dwelt.

The famous 'free' University of Perugia, founded in 1320, is now in a state of decline. It had, in 1901, two faculties, 26 teachers, and 320 students. Its library possesses 20,000 volumes. In addition there may be mentioned an Art History collection and a Botanic Garden, and the valuable university collection of Etruscan, Roman, and mediæval antiquities. There are in the city a lyceum, a gymnasium, a technical school, a seminary, an academy of fine arts, and an economic-agrarian institution. A large orphan asylum is the chief of its benevolent institutions. There are factories of silk goods, velvet, and spirits. In the commerce figure chiefly grain, wine, and oil. Three miles southeast of the city lies the Etruscan necropolis of Perugia, discovered in 1840, with remarkable tombs including the sepulchre of the Volumnii. Population in 1901, 61,385.

Perugia (anciently called *Perusia*) was one of the twelve important Etruscan League cities. It became Roman in B.C. 309. In B.C. 41-40 it was unsuccessfully held by the partisans of Antonius against Octavius (Perusian War). It was destroyed by Octavius and then rebuilt by him. It was again destroyed by Totila after a siege of seven years. Early in the Middle Ages it fell under the dominion of the popes, but it afterwards enjoyed a long period of independence, and at the close of the Middle Ages ruled Umbria. About the middle of the sixteenth century it was incorporated in the Papal States. It passed to the Sardinians in 1860 and became a part of the new Kingdom of Italy. Consult: Symonds and Gordon, *The Story of Perugia* (London, 1898); Cruickshank, *The Umbrian Towns* (ib., 1901).

PERUGIA, Lake of. A lake in Italy. See Trasimeno, Lago.

PERUGINO, pā-rōō-jē'nō, Pietro, properly Pietro Vannucci (1446-1523). An Italian painter, one of the chief masters of the Umbrian Schools during the earlier Renaissance. Born at Città della Pieve, a mountain town near Perugia, in 1446, Perugino was the natural heir of the traditions of the Umbrian School, the leading note of which was the atmosphere of sentiment and mystic poetry, which found its best expression in the portrayal of the ideals of devotional art. In 1455 he was apprenticed to a Perugian artist, probably Fiorenzo di Lorenzo, whose influence is manifest in his work. Benedetto Buonfiglio and Niccolò da Foligno have likewise been credited with his tutelage. According to Vasari, Perugino completed his studies under Verrocchio at Florence, but this seems unlikely in view of the severe tactile tendencies of Verrocchio's art and the unvarying Umbrian characteristics exhibited in Perugino's work. His first public commission was received in 1475 and related to the execution of certain frescoes for the Palazzo Communale in Perugia. From this time his rise was rapid, and when, in 1480, Sixtus IV. gathered together the best artistic talent in Tuscany and Umbria to embellish his newly completed chapel with fresco, although the company included such men as Rosselli, Ghirlandajo, and Botticelli, the major works were assigned to Perugino. The most important of these Sistine creations is the "Delivery of the Keys to St. Peter," a work showing great breadth of treatment, and peculiarly typical of his methods of bringing out the effects of space and atmosphere. The accurate knowledge of perspective, the feeling for the true values of distance, and the balancing and relation of these values make the work of Perugino peculiarly significant in view of the fact that these very elements of space composition were fundamental in the works of his pupil Raphael.

Perugino led a wandering life, but after 1502 he worked mostly in Florence, where he married and purchased a house, while retaining his citizenship in Perugia. In 1450 Perugino finished the decoration of the Sala del Cambio, Perugia, with frescoes allegorical of "Fortitude," "Temperance," "Justice," and "Prudence," and sacred subjects like "God, the Father," the "Nativity," and "Transfiguration." This work marks the height of his art. The "Marriage of the Virgin," now in the museum at Caen, belongs to this time. Painted for the cathedral at Perugia, it was the model of Raphael's production of the same subject. The most remarkable of Perugino's mural paintings, excepting those noted above, are the fresco of "Crucifixion," Santa Maria Maddalena, Florence (1492-1496), those at Città della Pieve, Panicale, Spello, and Trevi. Among the altar pieces may be selected "Virgin Enthroned" (1496), in the Vatican; the "Annunciation," Fano (1487); "Crucifixion," "Gethsemane," and "Assumption" (1500), from Vallombrosa, now in the Florence Academy; "The Vision of Saint Bernard," at Munich; the triptych painted for the Certosa, near Pavia, now in the National Gallery, London. His heads of "Two Monks of Vallombrosa" (Florence Academy) show him as a portraitist of high ability. His later pictures, of which he produced large numbers, show decline. The artist's last work, the "Nativity" (1522) from Fontignano, is now in the South Kensington Museum. He died of the plague at Castello di Fontignano in 1523.

PERUVIAN ANTIQUITIES. The social structure of Peru was not unlike that of the more primitive tribes to the north. There was a head chief or Inca, who had an advisory council elected by the various clans or gentes of the people. The office of Inca was hereditary in the female line.

The religion was based upon the worship of the sun as the supreme god, who according to the Peruvians had three sons: Kon or Viracocha, Pachacamac, and Manco Capac, the last the founder of the Incan Empire. It is, however, probable that the myths of Viracocha and Pachacamac antedate the Incas. Legend says that Viracocha (q.v.) signifies Foam of the Lake or Sea. One day he arose out of the waters of Lake Titicaca and created the sun, moon, and stars. He made stone statues, and, putting life into them, commanded them to follow him to Cuzco. After setting Allca Vica, the ancestor of the Incas, over them he disappeared in the water.

Pachacamac signifies 'He who animates the universe.' He was regarded as the being who created and ruled the world. In the valley of Rimac a vast temple was erected to this invisible god.

Next to the sun the Incas worshiped the moon, his sister and consort. Cuycha, the rainbow, was venerated as the servant of the sun and moon; Chasca, the planet Venus, as the page of the sun. The Pleiades were the next most venerated. Fire was worshiped as coming from the sun, and thunder as his servant. After these were many minor deities and *canopas*, which last correspond to the Lares and Penates of the Romans. The bloody rites so frequent in Mexico and Yucatan were unknown in Peru.

The Peruvians believed in the existence of the soul after death, and also in the resurrection of the body. The good were to live a life of luxury and ease; the wicked must expiate their crimes by ages of wearisome labor.

The Empire of the Incas was a perfect theocracy. The reigning Inca was not merely the representative of divinity; he was divinity itself, the law, and the law-giver, the violation of whose ordinance was sacrilege. The Inca appointed the chief priest, who in turn nominated all his subordinates. All the higher offices were filled by members of the Inca family. The virgins of the sun were young maidens dedicated to the service of the deity. They dwelt in convents under the charge of elderly matrons. These holy virgins were occupied in weaving the fine wool of the vicuña into garments for the Inca and hangings for the temples. In the houses of the virgins of the sun at Cuzco all the inmates, said to number 1500, were of royal blood. These virgins of the sun were brides of the Inca, and at marriageable age the most beautiful were transferred to the royal seraglio. The great nobles were also allowed a plurality of wives. At an appointed day of each year all those of marriageable age were called together in the great squares, throughout the Empire. The marriage ceremony consisted in joining the hands of the couples to be united. The Inca performed this ceremony for his own kindred, pronouncing them man and wife. His *curacas* performed a like office for those of inferior rank. Land was allotted to the newly wedded pair for their maintenance, and a dwelling was built at the charge of the district.

The land was parceled out to the various clans by whom it was owned in common, and under the wise system of administration everyone not incapacitated by age or other infirmity was obliged to be a producer. Agriculture was the basis of prosperity and was carried on carefully and thoroughly, with division of labor, irrigation, manuring, and terracing of rocky slopes, to make every tillable acre yield its full return. Their chief crops were maize, potatoes, yucca, quinoa, and cotton. Much attention was given to irrigation, aqueducts and canals crossing the low lands in all directions like a vast network. Dogs were kept as elsewhere, besides monkeys, birds, and guinea pigs, and the llama had been domesticated as a beast of burden and for its hair, from which, as well as from native cotton, were spun and woven the fabrics in common use.

Peruvian architectural structures composed of stone were characterized by simplicity, symmetry, and solidity. These stones, often huge boulders, were put together without mortar, but so exactly cut and fitted to each other that the blade of a penknife could not be forced between them. The Peruvians excelled as road-builders. Remains of many of these roads exist, the most important ones extended from Quito to Cuzco, and, diverging, continued in a southerly direction. In places galleries were cut, for miles, through solid rock, rivers crossed by swinging bridges, and ravines filled up with solid masonry. It is estimated that some of these roads, which were used

[illegible] were from [illegible]

[illegible] of textile fabrics the Peru- [illegible] peoples. [illegible] the very style of weaving [illegible] of their tapestry, in the ex- [illegible] of the weaving and beauty of [illegible] and designs, has probably never been excelled. They showed a degree of skill in other [illegible] arts similiar to that displayed in their manufacture of cloth. They have left behind them many remarkable evidences of their knowledge in working metals. They were familiar with the processes of smelting, casting in molds, hammering, and soldering. Tools and various objects of bronze were in use. In the ancient tombs have been found many elegant and curious objects of gold and silver, vases, cups, bracelets, collars, and personal ornaments. Emeralds they possessed in considerable quantity and these they cut with great skill. In the manufacture of pottery they attained to a high degree of excellence. Many of these vessels are beautiful in outline. Often they represent the human form or that of some familiar object or animal, and in the firing and decoration they show an advanced stage in the potter's art.

In music they had reached considerable proficiency, judging by the number and variety of the musical instruments left behind them. Among these are Pan-pipes, flutes of cane and bone, clay trumpets, trumpets of shell, bells of bronze and copper, and a great variety of whistles, capable of yielding a scale of several tones. It does not appear that they ever reached the more advanced stage of stringed instruments. Of the character of their vocal music we know nothing.

They had considerable knowledge of medicine and surgery, employing bleeding and purging. In astronomy they had made some progress, dividing the year into twelve lunar months. They also had weeks, but of how many days is uncertain. As their lunar year would necessarily fall short of the true time, they corrected their calendar by solar observations made by means of columns raised on the high lands at Cuzco. These served them for taking azimuths, and by measuring their shadows they ascertained the exact times of the solstices. The period of the equinoxes was determined by the help of a solitary pillar.

The ancient Peruvians, having no written language, made use of the *Quipu*, a device consisting of a main cord with others of different colors depending from it like a fringe. Each color denoted some object or abstract idea. *Quipu* signifies a knot. Knots tied in the depending cords served as ciphers, and by tying them at different distances from the main cord and from each other, they could be made to represent numbers to any amount required. These knotted cords were also used as mnemonic aids. There was also a considerable body of song, legend, and drama handed down by oral tradition. Among these the drama of *Ollantay*, committed to writing soon after the Conquest, has been translated into several languages.

The burial customs varied in different parts of the country. Believing in the resurrection of the body, the same care was everywhere exercised to preserve it. The mummies, or more strictly speaking the desiccated bodies [illegible] owe their preservation to the exceedingly dry and rarefied atmosphere of the mountains or the dry nitrous sand of the coast regions. In preparing the body for the grave, it was commonly placed in a sitting posture, with the knees drawn up and the chin and hands resting upon them. In the extreme northwestern part of Peru the body was buried in an extended position. The mummies of the better class were often covered with wrappings of fine cotton cloth; over this were ponchos and blankets made of the wool of the alpaca and vicuña. With them were placed vases of elegant design, and often objects of gold and silver. The cerements of the poor are scanty and mean, and the objects buried with them of inferior quality. Food was always placed with the dead, and generally the objects most prized in life. The last resting place varied with the locality. In some places vast mounds, penetrated by galleries, were raised over the dead. In others mummies are found in little vaults or chambers of adobe, roofed with sticks or canes, often containing four or five bodies. In the Callao and parts of Bolivia the burials were in stone chulpas or burial towers.

Scattered over the country are extensive ruins of ancient temples, convents, palaces, and burial places, many of which undoubtedly long antedate the Incan Empire.

The ruins of the so-called temple, convent, and palace at Tiahuanaco, near the southern extremity of Lake Titicaca, in Bolivia, are good examples of pre-Incan remains. Although but few stones of the structures are in position, enough remain to show their character and size. In these buildings copper clamps were used to hold the stones in position. The temple was rectangular in form, 445 by 388 feet. Here also is the famous monolithic doorway. The stone is 13 feet 5 inches long, 7 feet 2 inches high, and 18 inches thick. Through this is cut the doorway, 4 feet 6 inches high and 2 feet 9 inches wide. Scattered about the ruins are blocks of sandstone, trachyte, and basalt, many of them symmetrically cut and elegantly decorated. When Tiahuanaco was first visited by Europeans these structures had been in ruins for such a length of time that even native traditions were silent as to their builders.

At Pachacamac (q.v.) the Incas erected a magnificent Temple of the Sun, a House of the Virgins of the Sun, and a temple to Pachacamac. The temple was rifled of a vast amount of gold and silver by the Spaniards.

On the islands of Titicaca and Coati, in Lake Titicaca, are a number of famous ruins. The island of Titicaca was dedicated to the sun, and was the sacred island of Peru. Its most notable ruins are those of the Palace of the Incas, the Storehouse of the Sun, and the Bath or Fountain of the Incas. The Temple, a stone building 51 by 44 feet, and two stories high, is in a fair state of preservation. The walls were covered inside and out with stucco, and painted, as may be seen by patches still remaining on the stones. The large stone edifice called the Store-house by the early chroniclers gained its title from the darkness of its small rooms and connecting passages, which precluded the idea that it had been used as a habitation. The Bath or Fountain has suffered but little from time. It is a pool 40 by 100 feet, and 5 feet deep, paved with worked stones and fed by four streams of water from openings cut in the stone.

On the island of Coati (dedicated to the moon) are two groups of ruins. The principal of these,

the Palace of the Virgins of the Sun, is in a fair state of preservation. It is rectangular in form, 183 feet long by 80 broad. The structure, built of roughly cut stones, was two stories high. The first story is divided into thirty-five apartments of various sizes. The floors of the upper rooms, which were probably of wood, have disappeared. The second group consists of stone buildings with narrow passages between them. These and similar buildings on Titicaca are believed to have been used for ceremonies through which pilgrims were obliged to pass before visiting the sacred shrines.

At Cuzco the Temple of the Sun was said to have been the most imposing edifice in all Peru. Existing remains confirm the accounts of the early chroniclers. Surrounding the Temple were other buildings, dedicated to the Moon, Venus, the Pleiades, the Thunder and Lightning, and the Rainbow.

Among the other notable ruins of Peru may be mentioned those of the ancient city of Chimu, consisting of a labyrinth of ruined walls, dwellings and other structures, and gigantic *huacas*, or burial places; Sillustani with its *chulpas* or stone burial towers and sun-circle; the great fortress in the valley of Cañete, near Lima; those of Hervai, in the valley of Huareu (also near Lima), including a temple said to have been dedicated to the oracle-deity, Rimac; the rock tombs of Ollantaytambo, these tombs being excavations, natural or artificial, in the face of a high cliff, within which the dead were placed and walled up with stones, stuccoed over and painted. Here also are the ancient porphyry quarries, and the remains of numerous Inca walls and structures.

PERUVIAN ARCHÆOLOGY. The Spanish Conquest came at the height of the power of the Incas in Peru. This people was of Quichua stock and they had conquered the tribes of the present country as well as those of Bolivia, Ecuador, and Chile, and had subjected them to their remarkable organization. The Incas, at their beginning a clan of the Aymara, had their ancestral seats on the shores of Titicaca, where they built a number of cities, the greatest of which was Tiahuanaco. Comparatively few in number, they moved north and settled in the valley of Huilcamayo. After taking Cuzco, the home of an earlier culture, they grew more powerful, and began their conquest about the year 1200. At first sun-worshipers, they later became sun-worshipers, and fixed this cult upon the people whom they subjugated. The success of the Incas was due to their despotic commune, by which they fixed the people to the soil, and in return for the regulated labor of all insured the well-being of each. The organization consisted of a priest-king, a council, hierarchy, rulers of districts, and grades of officials. The growth of Inca power occupied about three centuries, and since their history is somewhat well known they occupy a disproportionate station among the peoples of Peru. It is known that other civilizations preceded that of the Incas to which they merely superadded their peculiar organization.

There are three well-marked races in Peru, which are associated with three civilizations. Of these the Kechua or Quichua (q.v.) occupied the region from the river Andasmayo, above Quito, to the Rio Maure in Chile, except a narrow area extending from the basin of Lake Titicaca to the coast. They were an inland people, living in the high mountain valleys, the basin of Titicaca, the Collao, and on the eastern slopes of the Andes, above the forested zone, from which they were excluded by the wild tribes. The Aymara (q.v.), who preponderate among the existing Indians of Peru, are of Quichuan stock. A second civilization displaced by the Incas is that of the Quito Kingdom of Ecuador, which was the northernmost extent of the Inca dominion, and whose inhabitants were the Cara of early writers. A third civilization was that of the Muchik, called Yunga by the Incas and Chimu by the Spaniards, of which Pachacamac (q.v.) was an important city. The Chimu kingdom extended from the Gulf of Guayaquil south to Callao, the port of Lima; also south of this was the domain of another related people and civilization.

It seems probable that the oldest civilization in Peru existed in the Collao south of Lake Titicaca, where are found the rude stone circles and dolmens of Sillustani, which resemble the monuments of Northern Europe. (See MEGALITHIC MONUMENTS.) It is thought by some writers that the authors of the highland culture came from the south, settling in the Collao, hunting the huanaco and practicing rude agriculture, and spreading into the basin of Titicaca, which has a prominent place in Peruvian origin myths. Thence they spread throughout the mountain region, having domesticated the llama and occupying the lower valleys for the purpose of raising maize. In the highland region are found the numerous evidences of Quichua greatness: the stupendous and elaborate ruins of Tiahuanaco (q.v.) and Pumapungu; the tombs of Sipa in the Santa Valley, formed out of cubical blocks of stone; Huanaco, where is a temple of five stories of rooms and corridors close against a mountain wall, and built of great blocks of carefully dressed stone laid in mortar, and adorned with statues; the statues of Chavin, like those of San Augustin in Colombia; the remarkable square or round *chulpa* or burial towers, found about Umayo Lake, in the Collao, and in Bolivia.

Quichua architecture is expressed in massive stone furnished by the environment, and grades from the rude monolithic structures of the Collao to the finely constructed and finished Temple of the Sun at Cuzco, at the best period. In plan the buildings were rectangular, inclosing rooms, or with rooms surrounding a court. There were

fo[illegible] buildings, except the doors, so that t[illegible] a blank appearance, unrelieved [illegible]ture or ornament. The door jambs [illegible] and each other so that the threshold is [illegible] than the lintel. This feature is invariable in Inca architecture. The non-use of the arch and the lack of timber did not prevent the erection of buildings of more than one story. The pitched roofs were probably of cane, thatched with reeds and grass. The houses of the people were flimsy structures that have not survived. In many places rock masses have been modified in a remarkable manner, the most common form being the so-called seats, which are single or in tiers. No obstacles seem to have balked the highland Peruvians; with their bruising tools of stone they shaped granite hills, tunneling, cutting steps, platforms, fountains, or tombs as they saw fit; at this day it is difficult to see the purpose of many of their works. One of the most complicated of these sculptures, thought to be a hygrometric observatory, is found at Quenco, near Cuzco. On the same grand scale are the reservoirs, baths, fountains, and aqueducts; the terraced fields, called *andenes*, covering the mountain sides; bridges, roads, and road inns or *tambos;* fortresses, prisons; sun dials, rock tombs, and *chulpa* tombs, which prevail in the track of the ancient highland civilization. On the objects connected with daily life, rather than in architectural decoration, this people lavished the art of the metal-worker, potter, and weaver, producing many designs expressive of a luxuriant fancy, but rarely showing a sense of the beautiful.

The coast peoples, the principal of which were the Yungas, occupied the hot valleys near the Pacific. Their country extended from the Gulf of Guayaquil south to Callao, but south of this was another related people in the same culture plane. They had solved the problems of the arid region by dividing the channels of the rivers and by other irrigation works, some of which are in use to this day by Peruvian planters. Guano, brought from the islands, was used to fertilize their fields, a practice which the Incas adopted from them. They also had boats of reeds provided with sails, and made in them considerable voyages along the coast. The highland people had such boats on Lake Titicaca, and it is believed that they were derived from the coast tribes. The coast civilization was ancient, and had begun to fade away long before the Incas became prominent on the highland. The last political organization of the coast was the Chimu kingdom, whose capital was Chanchan, or Gran Chimu, near Trujillo, the ruins of whose principal buildings cover about 250 acres, but the remains of other works thickly cover a plain six by twelve miles in extent. This city, which may be taken as typical of the coast culture, was laid out in the form of a long parallelogram, extending inland from the sea. The material used for construction is adobe formed in large blocks; stone is used sparingly in minor details. This, it will be observed, is earthquake construction, the coast suffering from violent earth movements. The city was divided into squares by cross streets; large buildings of labyrinthine plan, with [illegible] and numerous rooms, the whole structure having a single entrance, occupied many of the squares; others were occupied by great palaces. Excavations have shown that the inclosed labyrinthine [illegible]ards were the quarters of the artificers [illegible] and were in effect fortresses, probably each assigned to a different trade. The walls of Chimu have broad foundations of stone, the superstructure of adobe bricks, the walls narrowing toward the top. Decoration was by frescoes, rustic work, or by laying the adobes in checker, lattice, or arabesque patterns. The roofs were of cane, and a few beams of algaroba wood have been found in the ceilings of chambers.

On the plain of Chimu may be seen the embankment of the aqueduct supplying the city with water, its terminals leading to the fields and into the city. Sunken gardens made by clearing away the soil down to the moist layer are numerous. The most prominent landmarks on the plain are the three pyramidal cemeteries. These are cellular structures built of adobe and stone. The largest covers an area 580 feet square, or eight acres, and is 150 feet high.

In material civilization the Peruvians stand first among the aborigines of this hemisphere, but in intellectual progress they fall below the Mexicans, especially in the lack of writing, of which the *quipus* of knotted cords of different color poorly took the place. They had some knowledge of astronomy and metrology; the balance, it appears, was used. Their surgical knowledge is shown by the successful trephining practiced.

Artificial deformation of the skull was extensively practiced. The people were of low stature (1600 cm., 5 feet 3 inches), thickset and strong, not differing in this respect from the present Peruvian Indians.

PERUVIAN BARK. See CINCHONA.

PERUZZI, pā-rōōt'sē, BALDASSARE (1481-1536). An Italian architect and painter, the most gifted artist of the High Renaissance. He was born at Volterra, near Siena, March 7, 1481. Little is known of his early career, but from his work it is probable that he followed Il Sodoma and Pinturicchio in painting. In 1504 he went to Rome and speedily distinguished himself in frescoes in Sant' Onofrio—in the Vatican (ceiling of the Camera del Eliodoro)—and Santa Maria della Pace. Aided by Agostino Chigi, Baldassare studied the treasures of Rome, especially its architecture, and encouraged by Bramante, then in charge of the construction of Saint Peter's, became skilled in the elements of architectural design and composition. It is notable that in his detail especially he reflects the grace and sentiment of Umbria in his choice of profiles and ornament *motifs*, discarding the mechanized forms of Roman detail of the time of the Empire,

and choosing as his models the types used in the buildings of the Republic—forms which exhibit a delicacy of proportion and a pleasing individuality. In 1516 he designed for Agostino Chigi the Villa Farnesina, which was destined to become famous through the frescoes of Raphael and his school. The admirable frescoes on the ceiling of the room containing Raphael's Galathea are after his designs. In 1520 Leo X. appointed him, as the successor of Raphael, architect of Saint Peter's, and in 1525 he designed the Ossoli Palace, which shows an evident advance in the principles of planning. At the sack of Rome in 1527 Peruzzi was forced to paint a portrait of Bourbon, but upon its completion escaped to Siena, where he was made the city architect and superintended the construction of the Sienese fortifications. At this time he executed a number of frescoes and panel paintings, among which was the well-known "Augustus and the Sibyl" in the Church of Fontegiusta (Siena). His paintings are decorative in character, even to the sacrifice of truth to nature; they show the influence of Raphael and Michelangelo, and are apt to be mannered.

In 1532 he returned to Rome and commenced the building of the Massimi Palace, his architectural masterpiece, both in its general proportions and the variety of the detail and ornament. He carried on this work until his death in 1536, caused, according to tradition, by poison given by those envious of his position as architect of Saint Peter's.

Consult: Letarouilly, *Edifices de Rome moderne* (Paris, 1840-57); Donati, *Elogio di Baldassare Peruzzi* (Siena, 1879); Weese, *Baldassare Peruzzis Anteil an dem malerischen Schmucke der Villa Farnesina* (Leipzig, 1894).

PERUZZI, Ubaldino (1822-91). An Italian statesman, born in Florence. After pursuing the study of law at Siena, he went to Paris and Freiberg, where he devoted himself to the subjects of mathematics and mining. In 1848 he was appointed Gonfaloniere (chief magistrate) of Florence, but was removed in 1850 on account of his outspoken opposition to the reactionary policy of the Tuscan Government. He remained a warm advocate of liberal ideas and after the revolution of April, 1859, became a member of the provisional Government. After the annexation of Tuscany to the dominions of Victor Emmanuel, he was elected from Florence to the new Italian Parliament (1860). In 1861 he was Minister of Public Works under Cavour, and he continued in office under Ricasoli. Afterwards he held the post of Minister of the Interior in the Farini and Minghetti Cabinets. With Minghetti he went out of office in 1864, and thereafter acted as one of the Liberal leaders in Parliament.

PER'VIGIL'IUM VEN'ERIS (Lat., Night Watch of Venus). An anonymous poem of 93 lines, dating from the second or third century A.D., celebrating the power of Venus and referring to a nocturnal festival in her honor. It has been edited by Bücheler (Leipzig, 1859).

PESADO, pā-sä'dō, José Joaquin (c.1812-61). A Mexican poet and politician, born at San Augustin del Palmar. He was chiefly self-educated while living in Orizaba as a young man, became proficient in languages, science, and philosophy, entered politics in 1833 as member of the Vera Cruz Legislature, and five years afterwards was made Minister of the Interior. In 1854 he gave up his post as Foreign Minister, which he had held for eight years, to become professor of belles-lettres in the University of Mexico. He became joint editor of the paper *La Oposicion* in 1834, and wrote a novelette directed against the Inquisition, though religious subjects and Catholic sentiment prevail in his poems. Besides a collection of them, *Poesías originales y traducidas* (1839; 3d ed., 1886), he published a fragment, *La creacion* (1856), and a Spanish version of part of Tasso's *Gerusalemme liberata* (1860).

PESARO, pā'zä-rō. The capital of the Province of Pesaro e Urbino, Italy, situated at the mouth of the Foglia, on the Adriatic, and on the Bologna-Ancona Railroad, 29 miles northeast of Urbino (Map: Italy, G 4). It has broad streets, and is still partly surrounded by walls. Its fifteenth-century castle is now used as a prison. There are an old cathedral and a new cathedral, several palaces, including that of the dukes of Urbino, a public library of 35,000 volumes, a museum with collections of paintings and antiquities, a technical institute, and a musical lyceum, founded by Rossini, who was born here. The industries are silk-spinning, ship-building, and manufactures of ironware, earthenware, and machinery. There is a brisk shipping trade in figs, wine, oil, hides, grain, and cheese. Population (commune), in 1881, 20,909; in 1901, 25,103. Pesaro, the *Pisaurum* of the Romans, was founded in B.C. 184. It was destroyed by the Goths and restored by Belisarius and later formed a part of the Pentapolis. Pepin presented it to the Papacy. It came at the end of the thirteenth century under the rule of the Malatesta family, who sold it to the Sforza family in 1445. It was subsequently ruled by the Rovere dynasty of Urbino. In 1631 it reverted to the States of the Church, and since 1860 has formed a part of United Italy.

PESCADORES, pās'kä-dō'rās. A group of small basaltic islands situated off the western coast of the Japanese island of Formosa and on the Tropic of Cancer (Map: Japan, D 8). They cover an area of about 85 square miles and are mostly flat and barren. The largest of the group, Hokoto, has a good harbor. The inhabitants are engaged principally in fishing, and dried fish is the only export. Population, in 1898, 49,288, chiefly Chinese. The group was ceded to Japan, together with Formosa, in 1895, and is now an administrative dependency of Formosa.

PESCARA, pās-kä'rä, Fernando Francesco d'Avalos, Marquis of (c.1489-1525). A Neapolitan general in the Spanish service. He was taken prisoner by the French at the battle of Ravenna in 1512. During his captivity he composed poems addressed to his wife, Vittoria Colonna. Being soon after ransomed, he took part in several minor battles and contributed greatly to the victory over the French at Pavia in 1525, but was severely wounded. He commanded the army in Italy after the battle and was approached by Morone, the councilor of Francesco Sforza, Duke of Milan, in the interest of an Italian national party, since it was believed that Pescara was dissatisfied with Charles V. for not rewarding his services sufficiently. Pescara, however, betrayed the plot. He died soon after, November 30, 1525.

PESCHIERA, pās-kyā'rä. A fortified town in the Province of Verona, Italy, situated partly

on an island in the Mincio, and partly on the right bank of that river, on the Milan-Verona Railroad, 15 miles west of Verona (Map: Italy, I, 2). It was a member of the famous Quadrilateral (q.v.) until 1860. In the Middle Ages it was known as *Piscaria*, and belonged first to Verona and later to the Venetians, who strengthened its fortifications. Population (commune), in 1901, 2351.

PESCIA, pĕsh'ä. A town in the Province of Lucca, Italy, 29 miles west by north of Florence, on the Pistoia-Pisa Railroad (Map: Italy, E 4). It has a fourteenth-century cathedral, and an old castle, in which Galeazzo Visconti died in 1328. There are manufactures of silk, leather, paper, and hats, and a trade in wine, oil, and fruit. Population (commune), in 1881, 13,073; in 1901, 17,517.

PESELLINO, på'zĕl-lē'nō, or **PESELLO**, på-zĕl'lō, Francesco di Stefano (c.1422-57). An Italian painter, born in Florence. Little is known of his life, except that he was the grandson, and perhaps the pupil, of Giuliano d'Arrego. He first imitated Andrea del Castagno, and then Filippo Lippi. There is an "Adoration of the Magi" by him in the Uffizi Gallery, Florence, which shows his skill in painting animals. His other works include "The Trinity," in the National Gallery, London, and the predella (except the central panel, painted by Filippo) of the altar for Santa Croce, which is divided between the Accademia at Florence and the Louvre, Paris.

PESHAWAR, or **PESHAWUR**, pĕ-shä'wĕr. The capital of the newly formed northwest frontier province, British India, near the Kabul River, a tributary of the Indus 20 miles from the Afghan frontier, and 101½ miles east of the entrance to the Khyber Pass (q.v.) (Map: India, B 2). It is irregularly built with narrow winding streets, and is surrounded by a mud wall with watch towers. Although it dates from the fifth century, the city has few ancient monuments, and consists chiefly of mud houses. The cantonments contain a public garden, Christian churches, and a mission school. Peshawar is an important British military station, and is a great market; its bazaars are frequented by numerous Afghan and other Central Asiatic traders. It is the terminus of a railroad connecting it with the main railroad system of India. Population, in 1891, 84,191; in 1901, 95,147, of whom three-fourths are Mohammedans and 4000 Christians.

PESHIT'O, or **PESHIT'TO**. See Bible; section IV. *The Versions of the Bible—III. Aramaic.*

PESHWA, pĕsh'wä (Pers., leader). The Brahman ministers of the Mahratta dynasty of India. On the decline of the Mahratta rulers, the power of their ministers increased until in 1718 the first Peshwa, Balaji Visvanath, acting in the name of Maharaja Sahu, marched against Delhi to assist Farrukh Shah against the Mogul Emperor, Jehandar Shah. The Peshwa rule lasted for exactly a century. Balaji was succeeded in 1720 by his son, Baji Rao, who for twenty years was active in expeditions of conquest, even wresting Bassein from the Portuguese in 1739. He was followed in 1740 by his son Balaji Baji Rao, under whose administration the Mahrattas reached the acme of their greatness. They ravaged Northern India far and wide, levied *chauth*, or a quarter-tax, on Bengal, and were in formal possession of Orissa. In 1761, however, the last year of Balaji's life, the power of the Peshwas in Northern India was ended by their rout at Panipat by Ahmed Shah of Kabul, conqueror of the Punjab. Balaji was succeeded by his son, Madhu Rao, in 1761, who proved more than a match for Hyder Ali, and at the same time governed with remarkable order the Mahrattas themselves. In 1773, after the assassination of Narayan Rao, who ruled for a short time after Madhu's death, Raghunath Rao, a brother of Balaji Rao, became Peshwa. To defend himself against Narayan's posthumous son, Madhu Rao II., he was forced to call upon the English for aid. The first Mahratta War (1779-82) then broke out, in which Raghunath failed in his object, despite the aid of the English, and in 1782 he became a prisoner, while Madhu Rao succeeded him as Peshwa. Madhu committed suicide in 1795, after a puppet-reign, and was followed by Raghunath's son, Baji Rao II., the last of the Peshwas. To secure himself, Baji invoked English assistance, and by the Treaty of Bassein in 1802 ceded territory for the maintenance of the force given him. The result was an attack by the other Mahratta rulers, and the second Mahratta War (1803). This gave the Peshwa a prolongation of his rule, but he revolted in 1817. The third Mahratta War, which followed, ended in utter defeat for Baji and the extinction of the Peshwa power. His territory, which now forms the Bombay Presidency, was annexed by the English, and Baji Rao was a British pensioner until his death in 1853. His adopted son was the notorious Nana Sahib (q.v.). See Sindia.

PESNE, pän, Antoine (1683-1757). A French painter, born in Paris. He is said to have been a pupil of his uncle, Charles de la Fosse, and afterwards traveled in Italy. He lived most of his life in Berlin, where he was made Court painter to Frederick the Great, and director of the Academy. His portrait of the engraver Schmidt, in the Berlin Museum; his portrait of himself with his family (1718), in the New Palace, Potsdam; and the portrait of Vleughels, at Versailles, are familiar, vigorously painted pictures.

PESSIMISM (from Lat. *pessimus*, worst). The doctrine that life is or tends to become wholly undesirable, or that the world is essentially evil. It is thus contrasted with optimism, which teaches that the world is essentially good, and with meliorism, which maintains that the world is constantly becoming better and life more endurable.

Pessimism is characteristically a mental attitude toward life rather than a philosophical doctrine, and its significance is ethical rather than metaphysical. It never appears, however, except as a consequence of reflection and so of a certain amount of intellectual enlightenment. Most commonly it is the outgrowth of a consciousness of human impotence, and especially of the inadequacy of human effort in the struggle for ideal attainment. Where pessimism is based upon metaphysics, the world is usually conceived to be governed by blind necessity and human life to be a toy of fate. Accordingly the doctrine is most commonly maintained by those who hold a pantheistic conception of the universe, as the Orientals, or by those who conceive it as wholly determined by mechanical laws or as wholly

materialistic. Optimism, on the other hand, is a necessary corollary of belief in a beneficent God, and so is characteristic of theistic religions. (See LEIBNITZ for the argument.) At the same time there is a purely empirical pessimism—the denial that human life *per se* is worth while—which is compatible with any cosmological conception, whether theistic or not. Such a pessimism is that of the author of *Ecclesiastes*, and such a pessimism is the implied basis of Christian asceticism, by which physical life is valued only as a discipline for a more worthy existence.

Historically, philosophical pessimism has been of two leading types. Perhaps the most ancient is the pessimism of India, the essential character of which is the denial of the value of life on the ground that its pains overbalance its pleasures and progressively tend to do so with the growth of desire. This doctrine does not appear in the Vedic hymns; for these belonged to the restless, active period of the history of the Aryans in India, and activity is little compatible with pessimistic theory; but it early developed with Brahmanistic pantheism, and attained its full growth in Buddhism (q.v.). The salient features of Indian pessimism are: first, the assertion that life is predominantly painful; second, the notion that conscious evolution is dominated by growing desire and growing failure to attain satisfaction; and, third, the conception of Nirvana, or annihilation of individual consciousness as an ultimate relief from the fever of living.

In contrast to this Oriental pessimism stands the Greek type. This was faintly foreshadowed by the Platonic doctrine of the impotence of the material world in its efforts to attain the perfect good embodied in the divine ideas. Plato himself was saved from pessimism by the very vividness of his idealism; but with the philosophers who followed him the ethical problem became paramount and the problem of the existence of evil and the fact of human insufficiency were poignantly recognized. Epicurus (q.v.) is the typical Greek pessimist, his doctrine differing from the Oriental in that it denied the excellence of life in general and rather for its failure to achieve the good than for its mere painfulness. His practical doctrine, however—to make the best out of life by a temperate hedonism—speedily degenerated among his followers into a rough and ready sensuality. The most metaphysical and thorough-going of Greek pessimists was Proclus (q.v.), who taught that the whole evolution of the world is away from the divine or good.

But there was little congenial to pessimism in the exuberant paganism about the ancient Mediterranean; the classic peoples were too heartily in love with life. With the Teutonic Aryans the case was different. A gloomy fatalism was early characteristic of their myth and mood, and though the Northman looked forward to eventual annihilation in the cataclysmic contention of Ragnarok, the 'twilight of the gods,' rather than through passive absorption, his ultimate conception varied little from that of the Brahman. And the Teutonic point of view seems to have dominated mediæval Europe, giving it that ascetic pessimism which Christianity made empirical rather than ultimate. In modern times, however, pessimism has reasserted itself, largely under the influence of scientific determinism. The notion that the world is governed by invariable laws and conserves none but material elements has seemed to argue the defeat of the commonest human expectations. The pessimistic reaction has appeared most strongly in poets, as occasionally in Tennyson, for example, but notably in the Italian Leopardi (q.v.) and in James Thomson, the author of *The City of Dreadful Night*. In philosophy Schopenhauer and Hartmann (qq.v.) are the chief exponents of modern pessimism. The pessimism of the former is the result of his philosophic creed and is curiously eclectic in its origin. Schopenhauer as a follower of Kant believed that the world is a creation of experience to be idealistically interpreted; but according to his interpretation the creating power is a blind, uneasy, hapless-tending will, while intelligence is a suffering consequence of the will's activity. The painfulness of conscious life he endeavored to establish upon empirical, psychological grounds, and this feature of his pessimism is plainly Oriental in source. His further doctrine, however—that final escape from the misery of existence is to be attained through pure intelligence defeating the blind energy of the will by overcoming desire—seems to be allied not only to Brahmanism, but also to the Platonic doctrine of escape to the world of divine ideas and the Spinozistic theory of immortality through the soul's identification with eternal verities. (See PLATO; SPINOZA.) Schopenhauer's disciple, Hartmann, carried the doctrine further by arguing that the evolution of consciousness from an unconscious universe must ultimately result in an intelligence so acutely powerful that it should not only put an end to individual consciousness and desire, but compel the whole world's suicide.

It is but fair to state that pessimism is not necessarily a result of deterministic metaphysics, nor yet of pantheism. Herbert Spencer's meliorism teaches that the world is compelled to evolve desirable existence, and, indeed, that its essential activity is one of betterment; while Nietzsche, originally a disciple of Schopenhauer, finds optimistic inspiration in the Darwinian struggle for existence with its promise of the evolution of finer types of being; the necessity for pain he recognizes, but counts it of small import in comparison.

PESTALOZZI, pĕs'tä-lōt'sē, JOHANN HEINRICH (1746-1827). A Swiss educational reformer, and the chief founder of modern pedagogy, born at Zurich, January 12, 1746. As a student in the University of Zurich he allied himself with the young reformers of whom Lavater was the leader, and in a contribution to the *Memorial*, the organ of that faction, he expressed a wish that intelligible principles of education might be disseminated among his countrymen. He studied theology, then law, then, under the influence of the current naturalistic philosophy, and particularly Rousseau, turned to agriculture, with the avowed purpose of improving the condition of his countrymen by setting for them a good example in scientific agriculture, and, finally, when past middle life, began work as a teacher. He undertook to put in constructive form the ideas cast

by Rousseau in a destructive and critical form. It it was who tested the value of 'education according to nature.' Pestalozzi himself was unpractical and a bad organizer and manager, yet through his writings he aroused the Germanic peoples to the importance of social reform through education, and through his personal efforts he inspired a number of disciples who developed and carried out the principles of his practice until they became the basis of the educational movement of the nineteenth century. In 1767 he bought a hundred acres of poor land and erected a house thereon, naming the place Neuhof. Here he brought, two years later, his bride, and here for seven years he sought to demonstrate Rousseau's ideal life in a return to Nature. Though the experiment was a failure, yet in his attempt to educate his one child after the manner of the *Emile* he discovered the deficiencies of Rousseau's teachings, and later rejected the extravagances, and accepted the essential truths of the teachings of his master. Here also he wrote a 'Father's Journal,' which laid the basis of modern child study as an approach to the solution of educational problems. Undaunted by poverty and failure, and moved by the wretched state of the children of the poor, in 1775 he turned the farm into an asylum, where he housed, boarded, and clothed the children, in return for such work as they could give, thus hoping to regenerate his people by striking at the root of the evil through the industrial education of the young. The failure of this enterprise in 1780, due in a measure to the unsympathetic attitude of the parents of his wards, revealed to him the doubtful nature of the principle upon which it had been based, namely, that the reform of the individual and of the race could come through an improvement of the environment. Then followed a period of eighteen years of financial distress, and a corresponding period of great literary activity. During this time he gave up all practical efforts and devoted his energies to thinking out social and educational problems. The solution reached was that individual and social reform can come only through the moral and intellectual improvement of the individual by means of educational effort. In his *Abendstunde eines Einsiedlers* (published 1780) and his *Lienhardt und Gertrud*, the first volume of which was issued in 1781, he first presented this doctrine. The latter work, soon expanded into several volumes, was a novel descriptive of peasant life, which had an enormous popularity, since it fell in with the idealistic and revolutionary tendencies of the times.

The fundamental ideas of *Lienhardt und Gertrud* were that the condition of the people was to be bettered by education, not by revolution; that education was to centre in the home, and not in a separate institution; that this education was to begin at the cradle, and that the first few years were of the greatest importance; that an ignorant mother, by following the method given in his book, could educate her children as well as a teacher in possession of all science; that if homes were thus reformed, misery would disappear, and society would be revolutionized. From 1787 to 1797 Pestalozzi was again engaged in agricultural experiments. During this period he formed the acquaintance of Fellenberg and Fichte, and in 1792 was proclaimed French citizen with Klopstock and Washington. After the long period of literary work, during which Pestalozzi wrote 20 volumes, the exigencies of war forced him again into active life, and in 1798 he became director of an orphan asylum at Stanz, where he attempted to work out the ideas of *Leonard and Gertrude* (as the work is known in English), of combining learning with hand work, and centring it upon the objects of the child's immediate environment. It was along this line that Pestalozzi thereafter worked, and had his permanent influence. In 1799 he entered upon active schoolroom work at Burgdorf, and later at several other places. In 1802 Pestalozzi went to Paris as a member of the consulta summoned by Bonaparte to settle the fate of Switzerland, and while there memorialized the First Consul upon the educational needs of his country, but received the curt reply that there was no time to bother about A B C matters. He established the Institute at Yverdun in 1805, from which emanated the influence that was to give inspiration to all modern education. Here gathered not only the children of the schools, but great numbers of teachers from most of the leading States in Europe in a sort of normal school; here were sent by the Prussian Government the teachers that were to assist in introducing his ideas into the German Volksschulen. Even here his work as a practical teacher was unsuccessful, and in 1825 he was forced to withdraw as a broken-down and disappointed old man. He died at Brugg, February 17, 1827.

Pestalozzi never systematized his ideas or his method. In 1801 he published *Wie Gertrud ihre Kinder lehrt*, which purports to give a summary of his work, but it contains no definite formulation of either principle or method. His great effort, on the purely educational side, was, to use his own expression, to 'psychologize education.' To this effort is due the great attention that has been given to the study of method, both practical and theoretical, from that day to this. In Pestalozzi's passionate love, however, for his people, and particularly for children, and his readiness to sacrifice all personal interests for them, lies the secret of his powerful influence. This trait in his personality is what made him honored and loved by his contemporaries. The inspiration he affords to the struggling pedagogues is not the least of the benefits he conferred upon posterity.

Bibliography. In addition to many editions of single works, there is a complete edition in 18 volumes by Seyffarth (Berlin, 1881); *Lienhardt und Gertrud* has numerous translations or abridgments, as also *Wie Gertrud ihre Kinder lehrt*. Consult: De Guimps, *Pestalozzi, His Life and Works* (New York, 1889); Barnard, *Pestalozzi and Pestalozzianism* (ib., 1862); Krüsi, *Pestalozzi, His Life and Works* (ib., 1875); Pinloche, *Pestalozzi* (ib., 1901).

PESTALOZZIAN MOVEMENT. A term sometimes applied to the modern tendency to base schoolroom instruction on psychologic principles. It dates from the days of Pestalozzi (q.v.). This movement began in Germany in the early part of the nineteenth century and was initiated in the United States by Horace Mann (q.v.). See Pedagogy; Education; Pestalozzi.

PESTH, pēst. A city of Hungary, now united with Buda to form Budapest (q.v.).

PESTILENCE (OF., Fr. *pestilence*, from Lat. *pestilentia*, plague, from *pestilens*, infected, from *pestis*, pest). The terms plague and pestilence have until recent times been used indiscriminately to denote any diseases of an epidemic character which affected large masses of the community, and were remarkable for their fatality, such as the Oriental plague, the sweating sickness, cholera, certain virulent forms of fever, etc. The term *loimos* was applied by the Greeks to a species of epidemic remittent fever; and the plague of Athens described by Thucydides is manifestly an epidemic form of the same disease, which is endemic in the summer season on the coasts and islands of the Mediterranean and particularly the Archipelago. We find in the early history of the colonization of the West Indian islands and the United States frequent examples of the term plague being applied to the remittent fever of these regions, and especially to epidemic attacks of yellow fever. During the Middle Ages the term *pestis* was applied to numerous disorders, such as syphilis, smallpox, erysipelas, epidemic sore throat, petechial fever, the sweating sickness, gangrenous pneumonia, ergotism, etc. The Black Death of the fourteenth, fifteenth, and sixteenth centuries was the bubonic plague; and the Great Plagues in China in the fourteenth century were probably also bubonic.

Several Hebrew words are translated *pestilence* or *plague* in the Old Testament. Some of these pestilences are beyond the reach of inquiry; others have the characteristics of modern epidemics. See BLACK DEATH; PLAGUE.

PETAL (from Gk. πέταλον, *petalon*, leaf, neu. sg. of πέταλος, *petalos*, outspread). One of the individual parts of the corolla (q.v.). See FLOWER.

PET'ALESHA'RO. A Pawnee chief of the Skidi band who distinguished himself by an act of humane bravery in rescuing a captive girl who was about to be sacrificed by his tribe. The captive, a girl taken from the Sioux tribe, was being led to the scaffold when Petalesharo, who as yet was only a young warrior, broke through the circle, seized the girl, and, throwing her upon one of two horses which he had in waiting, was off with her before the people could recover from their surprise. Distancing pursuers, he escorted her to a place of safety near her own country, and then left her to find her way home on the horse which he gave her. On returning to his village he faced the anger of the tribe with such boldness that he was allowed to go unharmed, and was ultimately able to break up the practice of human sacrifice by procuring the substitution of a vicarious ceremony. On subsequently visiting Washington as a delegate from the Pawnee in 1821 he was presented with a medal by the ladies of the city in recognition of his services to humanity. See PAWNEE.

PETARD (OF. *petard*, *petart*, Fr. *pétard*). A device for demolishing the defenses of an enemy, creating a breach through which the besiegers may force an entry. Under modern conditions it has become obsolete. It consisted of a half cone of thick iron filled with powder and ball, and fastened to a plank which was provided with hooks, by which it could be attached to a gate or wall. The engineers attached the petard, lighted the slow-burning match by which it was to be fired, and retired. When the explosion took effect a supporting column charged through the breach, and took advantage of the confusion within. A petard would sometimes contain fifteen pounds of powder.

PETA'VIUS, DIONYSIUS, or DENIS PÉTAU (1583-1652). A French theologian and philologist, born at Orleans. His father, a man of learning, encouraged his studies, and he took up mathematics and belles-lettres, also philosophy, which he pursued both at Orleans and Paris. During his student years at Paris he formed a warm friendship with Isaac Casaubon (q.v.), whom King Henry IV. had invited to Paris in 1600. In 1602 he accepted the chair of philosophy in the University of Bourges, but resigned in 1605 and entered the Jesuit Order at Nancy. He studied theology for two years at the College of Pont-à-Mousson, and in 1621 became professor of *theologia positiva* at the University of Paris, and held the post for twenty-two years. He is regarded as one of the greatest scholars the Jesuit Order has possessed. In philology his works include annotated editions of Synesius (1611), Themistius (1613), Julian (1614), Nicephorus (*Breviarium Historicum*, 1616), and Epiphanius (*Opera Omnia*, 1622). In his *Opus de Doctrina Temporum* (Paris, 1627) he presented a new system of chronology, further developed in *Uranologion* (1630). A history of the world, *Rationarium Temporum* (1633), from the earliest times down to 1632, has been reprinted as late as 1849. His great work, a history of doctrines, *Opus de Theologicis Dogmatibus*, 5 vols. (1644-50), was left unfinished. Consult his *Life* by Stanonik (Gratz, 1876).

PETCHARY, pĕch'ā-rĭ (West Indian name, onomatopoetic in origin). An old book name for the large tyrant flycatchers of the West Indies, known elsewhere as kingbirds. The term has survived, however, in Jamaica for the gray kingbird (*Tyrannus Dominicensis*), and especially for *Tyrannus caudifasciatus*, one of the most common birds of the West Indies, often shot in the fall as a table delicacy. See KINGBIRD.

PETCHORA, pā-chō'rā. A river of Northern Russia. It rises on the western slopes of the Ural Mountains, in the Government of Perm, and flows northward through the Government of Vologda and a part of Archangel; then it turns to the southwest and finally resumes its original course at the mouth of its tributary the Tzilma, and enters the Arctic Ocean through an extensive delta, containing numerous islets (Map: Russia, H 1). Its entire length is estimated at from 1000 to 1300 miles, of which about two-thirds is navigable. The chief tributaries are the Koshva, Ishma, Ussa, and Tzilma. The region through which the river flows is known as the Petchora or Arctic steppes, and is very sparsely populated. The Petchora is of considerable importance as a navigable waterway, being used for the transportation of the products of the north—fur, fish, etc.—into the interior, from which grain and other necessaries of life are sent in return into the northern districts.

PETECHIA, pē-tēk'ĭ-ā (Neo-Lat., from It. *petechia*, spot, scab, from Lat. *petigo*, scab, or from Lat. *pittacium*, from Gk. πιττάκιον, *pittakion*, label, plaster). A name given to a spot of a dusky crimson or purple color, quite flat, with a well-defined margin, and unaffected by pressure, which closely resembles flea-bites.

Petechiæ result from a minute extravasation of blood beneath the cuticle. They may occur on any part of the skin or mucous membranes, and when large are called ecchymoses. They indicate an altered state of the blood, and are often symptoms of very serious diseases, as of typhus fever, plague, scurvy, etc. They likewise occur in very severe cases of smallpox, measles, and scarlet fever, when their presence must be regarded as indicative of extreme danger. Cerebro-spinal fever is sometimes called 'petechial fever,' from the small hemorrhagic spots which cover the body in certain cases.

PETER (Lat. *Petrus*, from Gk. πέτρος, Peter, πέτρος, rock), or SIMON PETER. The Apostle of Jesus who is named first in each of the lists of the Twelve in the Synoptic Gospels. His original name was the Hebrew *Shim'ôn*, which was easily shortened to conform to the Greek Simon. He was the son of a certain Jona and (cf. John i. 44) was a native of Bethsaida. In his early manhood he was a citizen of Capernaum. Here he had a house, and with his brother Andrew was engaged in the fishing business in partnership with Zebedee and his sons (Mark i. 16-31, and parallels). He was married, but whether he had any children is not known. It is likely that he was a man of some property, not a poor, grossly ignorant laborer, though he was not rich. Of his early education and attainments we know nothing. Galilee, his home, was practically a bilingual country, with a fair degree of Greek culture possessed by the Gentile elements of the population. Hence Peter had opportunity for becoming acquainted with colloquial Greek, and there is no good reason for supposing that he was unable to use his Greek Old Testament intelligently.

When the news of the preaching of John the Baptist reached Galilee Peter and Andrew went to hear him. They were impressed and attached themselves to him as at least temporary disciples. Here they became acquainted with Jesus, who gave to Simon the surname Cephas, i.e. *rock*, or, in Greek, Peter (John i. 35-42). After continuing with Jesus a while the brothers returned to their accustomed occupation. Soon after He opened His public ministry in Galilee Jesus summoned them from their nets to a permanent discipleship (Mark i. 16, and parallels). They at once left all and followed Him. Into the details of Peter's experiences during his two years' intimate association with Jesus we cannot enter. The many incidents recorded in the Gospels give a fairly adequate idea of his general character and disposition. He was a whole-hearted though often blundering disciple. His willingness to be taught enabled him finally to grasp certain great essentials of Jesus' character and mission, so that Jesus could say that he was the 'rock' on which he would build His Church (Matt. xvi. 18). He was one of the three disciples with whom Jesus was most intimate, who alone witnessed His transfiguration (Mark ix. 2-10) and agony in Gethsemane (Mark xiv. 33). Thoroughly convinced of Jesus' Messiahship, even when the tide of popular favor had begun to ebb, he was yet in great need of enlightenment as to what it really signified (Mark viii. 29-33). His impulsive nature led him to deny his discipleship when Jesus was on trial, but his deeper and more permanent love for his Master soon reasserted itself, and he returned to the scene and was an eyewitness of the Passion (cf. I. Peter v. 1, and the article PETER, EPISTLES OF). He was the first of the Apostles to whom Jesus revealed Himself after His resurrection (I Cor. xv. 5; cf. Luke xxiv. 34), was present at most of the post-resurrection interviews between Jesus and the disciples, and to him in particular Jesus tenderly and suggestively reintrusted his apostolic commission, at the same time intimating the self-denial and suffering that awaited him in his future career (John xxi. 15 sqq.).

After the departure of Jesus Peter was easily recognized as one of the leading spirits of the little company of believers who were hoping for something, just what they did not know, and who formed the nucleus of the Church. It was he who suggested the appointment of Matthias to take the place of Judas Iscariot, and a few days later, on the day of Pentecost, made the first public attempt to explain and set forth the claims of Christianity and urge its acceptance upon his fellow Jews (Acts i. and ii). During the next few years, when the first converts were being secured and the first steps in organization planned, Peter seems to have been the most influential man in the Church. His fellow worker and most intimate friend was John. When Christianity spread beyond the bounds of Jerusalem into the various districts of Palestine, Peter and John, and afterwards Peter alone, rendered efficient aid by visiting and further instructing the new converts. In Samaria, on such a visit, he came in contact with the local magician Simon Magus (q.v.), a professed convert, whose ignorant cupidity he sternly rebuked (Acts viii. 20). Another such tour led him as far as Joppa, on the coast, whence, by divine guidance, but against his prejudices, he went to Cæsarea to proclaim Christianity to Cornelius, the Gentile centurion. He received him and his house in Christian fellowship, and set aside his prejudices so far as to sit at table with them, something he had never before done (Acts x.). For such conduct an explanation was demanded by some in the mother church. Though it was pronounced satisfactory, it is probable that certain ultra-conservatives did not approve of what had been done (Acts xi.).

Up to the attempt of Herod Agrippa I. to put him out of the way, i.e. near 44 A.D., or for about 15 years (cf. Acts xii. 3 sqq.), it is probable that Peter made his headquarters in Jerusalem. He was the one member of the Apostolic band whom Paul, three years after his conversion (37 or 38 A.D.), went to Jerusalem to consult (cf. Gal. i. 18). Paul was with Peter 15 days, and in that time was doubtless given a full account of the earthly career of Jesus as complete as Peter's memory allowed. This notice from Paul's own letter is weighty evidence as to Peter's influential position in primitive Christian circles.

After his escape from Herod he left Jerusalem. We know nothing more of him until the time of the Council of Jerusalem (49 A.D.). Here he urged a liberal attitude toward Gentile Christians. With James and John he gave Paul and Barnabas the right hand of fellowship. Soon after this he seems to have visited Antioch (Gal. ii. 11 sqq.), and, true to his principles, fellowshiped heartily with the Gentile members of the Church there, making no distinction between them and himself. But when overzealous emissaries from James of Jerusalem came to Antioch

and insisted that the two classes should not eat together Peter vacillated, and weakly submitted to their dictation. This brought forth a sharp and well-deserved public rebuke from Paul (Gal. ii. 14 sqq.). There is no reason to suppose that this resulted in any lasting personal animosity betwen the two. Of Peter's further career we possess almost no information. It is probable that he was occupied in missionary labors, mainly among Jewish communities, in accordance with the agreement noted in Gal. ii. 9. On his journeys he was accompanied by his wife (I. Cor. ix. 5). If the word 'Babylon' (I. Peter v. 13) is to be taken literally, he must have labored mainly in Eastern Syria and the Tigris-Euphrates Valley. But 'Babylon' may be only another name for Rome. In I. Cor. i. 12 (written about 55 A.D.) reference is made to a 'Cephas' party in the Corinthian Church. But this does not imply necessarily that Peter had personally visited Corinth. On the other hand, the absence of any reference to him in Paul's letter to the Roman Church (of about the same date) does not make it certain that Peter had not been or was not then or soon after in Rome. The Apostles did not promptly inform each other of their respective movements. The view that Peter wrote I. Peter at Rome about 54 A.D. to Jewish and other Christian communities of Asia Minor has no decisive evidence against it, and of the corresponding view that II. Peter was likewise sent from the same city, but at least ten years later and to a different circle, the same may be said. The whole matter of Peter's presence in Rome at any time rests, it must be admitted, on a very insecure foundation. There is no positive evidence to that effect in the New Testament, and the earliest notice of Peter in early Christian literature (I. Clement v.) is equally indecisive. The next earliest notice (Ignatius, *Ep. ad Rom.*, IV. 3), about 110 A.D., is almost as vague. Later writers (Justin Martyr is a notable exception) generally represent Peter as having labored long and suffered martyrdom in Rome. While obviously unhistorical legends, such as those relating to his controversy with Simon Magus, have grown up in order to fill out a complete story, his residence in Rome for a longer or shorter period is usually accepted, not only by Roman Catholics, but by Protestant scholars of high rank. That he was martyred under Nero about the year 64 is probable, though not certain. Tradition relates that he met his death by crucifixion, but at his own request with his head downward, counting himself unworthy to suffer exactly in the same way as his Master. Roman Catholics reckon St. Peter as the first Bishop of Rome and the first Pope. Consult the works referred to under PETER, EPISTLES OF, especially the extensive bibliography by Chase in the Hastings Dictionary of the Bible; also Lightfoot, "Saint Paul and the Three," in his *Commentary on Galatians* (London, 1865); id., *The Apostolic Fathers*, Part I., Clement of Rome (ib., 1890); Lipsius, *Die apokryphen Apostelgeschichten* (Brunswick, 1887); Schmid, *Petrus in Rom* (Lucerne, 1892); Felten, *Die Apostelgeschichte* (Freiburg, 1892); Fouard, *Saint Peter* (London, 1892).

PETER I., ALEXEYEVITCH (1672-1725). Emperor of Russia from 1682 to 1725, generally known as Peter the Great. He was the son of the Czar Alexei Mikhailovitch by his second wife, Natalia Naryshkin, and was born at Moscow, June 9 (May 30), 1672. Peter's half-brother Feodor, who succeeded his father in 1676, died without issue in 1682, having named Peter as his successor, to the exclusion of his own full brother, Ivan, a feeble-minded prince. The Grand Duchess Sophia, Peter's half sister, attempted to set aside this arrangement and to obtain control of affairs. To this end she brought about an insurrection of the Streltsi (q.v.), and after much bloodshed Ivan and Peter were crowned as joint rulers and Sophia became Regent (July, 1682). Peter's education was not carefully looked after, and at an early age he gave evidence of those stormy passions which were to characterize his entire life. In February, 1689, Peter married Eudoxia Feodorovna Lapukhin, and soon after he called upon his sister to resign the government. This she would not do without a contest, and Peter was forced to flee from the capital, but the foreigners in the Russian service, led by Lefort and the Scotchman Gordon (q.v.), joined his party, and when the Streltsi deserted her the Regent yielded and was shut up in a convent. On October 11, 1689, Peter made his public entry into Moscow, where he was met by Ivan, to whom he gave a nominal precedence, reserving the sole exercise of power for himself. Ivan died in 1696. Peter was the first of Russian sovereigns to grasp the value and significance of Western civilization. He at once began the slow task of forming out of the barbarous and undisciplined material available an army on the European model. His ambitions were chiefly directed, however, toward creating a navy and developing the commerce of his country. Russia had no practicable seaboard, being shut out from the Baltic by Sweden, which possessed Finland, Ingermanland, Esthonia, and Livonia, and from the Black Sea by Turkey; leaving only the White Sea and the Arctic Ocean, with the solitary port of Archangel, available for a Russian navy. Peter therefore set on foot what has become the established Russian policy, of seeking in every direction an outlet into ice-free seas. The Black Sea seemed to him to be the most available for a first move. He launched Russia upon her career of warfare against the Turks, and succeeded in making himself master of the city of Azov, at the month of the Don, in 1696. Peter brought in engineers, naval architects, and ordnance experts from Austria, Venice, Prussia, and Holland; built ships; improved the equipment and discipline of the army; and sent many of the young nobility to study in foreign countries. After repressing a revolt of the Streltsi in February, 1697, Peter put the administration into the hands of a council and left Russia in April, traveling as a subordinate member of an embassy, headed by Lefort, for the purpose of acquiring at first hand the knowledge necessary to develop his Empire. He thus visited the Baltic provinces, Prussia, and Hanover, and subsequently Holland, where at Amsterdam and Saardam he worked as a common shipwright. On the invitation of William III., King of England, he visited that country, remaining for three months. He left England in April, 1698, taking with him about 500 English engineers, surgeons, and artisans, and visited Vienna for the purpose of inspecting the Austrian army. His travels were cut short by a second revolt of the Streltsi, which necessitated his return to Russia in Sep-

[illegible] 1698. General Gordon had crushed the [illegible] but Peter determined to be finally rid of [illegible] turbulent soldiery, and the organization was [illegible] up and its members executed in large [illegible] bers. Peter divorced the Czarina Eudoxia, [illegible] with his sister Martha was suspected of [illegible] complicity in the outbreak, which had been fostered by the Old Russian Party. The process of introducing Western civilization continued. Printing and education were promoted, the calendar was partially reformed, and Western methods of enumeration were introduced. Systematic taxation of commodities was adopted as a source of revenue; foreign commerce was encouraged; and much of the Orientalism in dress, manners, and customs which had grown up during the Mongol supremacy gave place to the ways of the Occident. The Church was reorganized, its government being intrusted to the Holy Synod, of which the Czar was the head.

Having secured to Russia access to the sea on the south, Peter turned his eyes toward the Baltic, the possession of whose shores he determined to dispute with Sweden. That kingdom since the time of Gustavus Adolphus had been the strongest military power in Northern Europe. In 1700 Peter made an alliance with Sweden's enemies, Denmark and Poland, and threw down the gauntlet in the struggle for the Baltic supremacy. He was badly defeated by Charles XII. at Narva, where his raw troops, although vastly superior in numbers, were wholly unable to cope with the Swedish veterans (November 30, 1700). Peter was not disheartened. Taking advantage of the Swedes being employed elsewhere, he seized a portion of Ingermanland, in which he laid the foundation of the new capital, Saint Petersburg (1703). Great inducements were held out to those who would reside in it, and in a few years it became Russia's commercial depot for the Baltic. For a long time in the contest with Sweden the Russians met with defeat, but Peter saw that reverses were administering to his troops a wholesome discipline. In 1709 Charles XII. rashly invaded South Russia, and on July 8th his army was annihilated by the Czar at Poltava. This event marked the collapse of the Swedish power. In the following year Peter was master of Livonia. He now found himself at war with the Turks, whom Charles XII., who had taken refuge among them, had stirred up to hostilities. In 1711 Peter was caught in a trap on the Pruth and was forced to conclude the Treaty of Hush (July 23d), by which he gave up the port of Azov and the territory belonging to it. On March 2, 1712, Peter's marriage with his mistress, Catharine (see CATHARINE I.), was celebrated at Saint Petersburg, and two months afterwards the central Government was transferred to the new capital. The war against Sweden was prosecuted with energy and success. In 1713 the Swedish general Stenbock was forced by the Danes, Saxons, and Russians to surrender at Tönning, in Schleswig. About the same time the Russians made themselves masters of Finland, and in 1714 the Russian fleet overwhelmed the Swedes near the Åland Islands. In 1716 and 1717 Peter made another tour of Europe. In 1718 a widespread conspiracy looking toward the undoing of Peter's reforms was discovered and among those implicated was the Crown Prince Alexei Petrovitch (q.v.). Peter caused his son to be sentenced to death, but pardoned him later. The unfortunate prince, according to the most probable accounts, died in prison from the effects of the torture to which he had been subjected. In 1721 peace was made with Sweden, which surrendered to Russia Livonia, Esthonia, Ingermanland, Karelia, and a small portion of Finland, together with all the islands along the Baltic coast from Courland to Viborg. In the same year Peter assumed the title of Emperor of All the Russias. In 1722 Peter commenced a war with Persia in order to open the Caspian Sea to Russian commerce. Derbend and Baku were the fruits of this war. The last years of Peter's life were chiefly occupied in beautifying and improving his new capital, and carrying out plans for the diffusion of knowledge among his subjects. In the autumn of 1724 he was seized with a serious illness, the result of his imprudence and habitual excesses; and after enduring much agony, he died, February 8 (January 28), 1725.

Upon the political life of Russia Peter the Great left a powerful impress, and though many of his social reforms proved in the end unadapted to the nature of the Russian people, he nevertheless must be regarded as the creator of modern Russia, which he first brought into the state system of European nations. The 'testament' attributed to him, defining his policy, is probably spurious, but it doubtless expresses, with some elaboration, his ideas. Consult: Schuyler, *Peter the Great* (New York, 1884), one of the best biographies in English; Motley, "Peter the Great," *North American Review* (October, 1845), a notable essay, since republished; Mintzlof, *Pierre le Grand dans la littérature étrangère* (Saint Petersburg, 1872), containing bibliographical notes on 1200 works not Russian relating in some way to Peter; Bergmann, *Peter der Grosse* (Königsberg-Riga-Mittau, 1823-30); Barrow, *The Life of Peter the Great* (London, 1873); Brückner, *Peter der Grosse*, in the Oncken series (Berlin, 1879). Among Russian works, mention should be made of Solovieff, Milionkoff, and Philippoff.

PETER II., ALEXEYEVITCH (1715-30). Emperor of Russia from 1727 to 1730. He was the son of Alexei, heir of Peter the Great, who perished in prison, and was born in Saint Petersburg, October 22 (11), 1715. He ascended the throne on the death of Catharine I., May 17, 1727, and immediately fell under the influence of the ambitious Menshikoff, who affianced the youthful Czar to one of his daughters. Menshikoff, however, was soon overthrown by the Dolgoruki, who succeeded to his power. Peter was crowned in 1728, and in the following year was betrothed to a member of the Dolgoruki family. The marriage was set for February 2, 1730, but a few days previously the Czar was stricken down by smallpox and died on February 9 (January 29). He was succeeded by Anna Ivanovna (q.v.).

PETER III., FEODOROVITCH (1728-62). Emperor of Russia in 1762. He was a grandson of Peter the Great by his daughter Anna, who was married to Duke Charles Frederick of Holstein-Gottorp, and was born at Kiel, March 3 (February 21), 1728. By the Empress Elizabeth Petrovna (q.v.) he was nominated successor to the throne. In 1745 he married Sophia Augusta, a princess of Anhalt-Zerbst, who, on entering the Greek Church, assumed the name of

Catharine. Peter succeeded Elizabeth on her death, January 5, 1762. His first act of authority was to withdraw from the alliance with France and Austria against Prussia, restoring to Frederick II. the province of East Prussia, which had been conquered during the Seven Years' War, and sending to his aid a force of 15,000 men—a line of conduct which seems to have been prompted solely by his admiration for the Prussian sovereign. He also recalled many of the political exiles from Siberia, among whom were L'Estocq, Münnich, and Biron, Duke of Courland; abolished many of the oppressive police laws; reduced taxation; initiated measures for the revival of Russian industries and commerce; and attempted a reorganization of the army and navy. He also attempted to reconquer for the House of Holstein-Gottorp the portion of Schleswig which had been ceded to Denmark in 1713. Peter's pro-German tendencies, however, his liberal policy, his indifference to the Greek Church, and his ill-concealed contempt for Russian manners and customs, made him hated by his subjects. His wife had still deeper cause for dislike: for though he was himself addicted to drunkenness and debauchery, he never ceased to reproach her with her infidelities, and had even planned to divorce her, disinherit her son Paul (q.v.), and elevate his mistress, Elizabeth Vorontsoff, to the throne. A formidable conspiracy, headed by Catharine, and supported by the principal nobles, was formed against him. On the night of July 8, 1762, Peter was declared to have forfeited his crown, and his wife was proclaimed Empress as Catharine II. by the guards, the clergy, and the nobility. Peter, who was then at Oranienbaum, neglecting the counsels of Field-Marshal Münnich, who proposed to march at once on the capital at the head of the regiments which were still faithful, soon found even the opportunity of flight cut off, and was compelled to submit. He abdicated the throne on July 9th, and on the 17th of the same month was put to death by Gregory Orloff to secure the safety of the conspirators.

PETER I., KARAGEORGEVITCH (1846—), King of Servia. He was born at Belgrade in 1846. His grandfather was George Petrovitch, known as Kara (Black) or Czerny George (q.v.), who led the Servians in their struggle for independence against the Turks, and in 1812 was recognized by the Sultan as Prince of Servia. Peter's father Alexander was elected Prince of Servia in 1842, to succeed Michael Obrenovitch, but in December, 1858, he was declared deposed by the National Assembly, and in the following month left the country. With him went Peter, who was put to school in Hungary, made frequent visits to Russia, and finally entered the French military school of St. Cyr. He graduated there and became an officer in the French army. After the outbreak of the Franco-German war he served with distinction under Bourbaki, notably before Villersexel. Three times he was captured by the Germans and as often escaped. For several years he followed a life of extravagance and dissipation in Paris, and then, aroused by the troubles in the Balkans, actively encouraged the rising of 1875-76 in Herzegovina, which culminated in the Russo-Turkish war of 1877-78 and the complete establishment of Servian independence. After a period of roving he went to Montenegro, and in August, 1883, married the Princess Zorka (born 1864), eldest daughter of Prince Nicholas. Eventually this marriage served to connect him with the Russian and Italian courts, since Zorka's sister Militza married the Grand Duke Peter Nikolaievitch and her sister Helena became the consort of Victor Emmanuel II. The permanent residence of Peter and Zorka was at Cettinje, but frequent visits to Paris were made. After Zorka's death (1890), Peter became estranged from his father-in-law and went to Geneva to educate there his three children, a girl aged five and two boys aged three and two. From that time until 1903, though a recognized 'pretender,' he lived quietly in Switzerland. On June 11, 1903, King Alexander of Servia, of the rival house of Obrenovitch (q.v.), and Queen Draga were murdered, and four days later Peter was elected King of Servia by the Skupshtina. After an absence of forty-four years he entered Belgrade on June 24th and on the following day took the oath of office. He was credited with liberal views and with pro-Russian sympathies. See SERVIA.

PETER OF BLOIS, blwä (c.1135-c.1208). An English prelate and author, born at Blois of a Breton family, and well educated at Paris and Bologna. For two years he was tutor to William II. of Sicily and keeper of the royal seal, and about 1173 entered the employ of Henry II. of England, who sent him to Paris and to Rome. Peter became secretary to the Archbishop of Canterbury in 1176, a post he continued to hold under Baldwin, who succeeded to the see in 1184, and in whose behalf he was employed at Rome for a time. After the death of Henry II., Peter acted (1191-95) as secretary to Queen Eleanor. He had been appointed Archdeacon of London in 1192, and, if he be identified with the Canon of Ripon bearing the same name, must have lived as late as 1208. He was a vain and ambitious man, well versed in Latin, and a very able secretary, as he could dictate three letters and write a fourth himself simultaneously. Among his many works the *Epistles*, published in 1480 at Brussels, are of the most worth.

PETER THE CRUEL, King of Castile. See PEDRO THE CRUEL.

PETER THE HERMIT, or PETER OF AMIENS (c.1050-1115). The preacher of the First Crusade. He was born in the city or at least in the diocese of Amiens about 1050. The stories told of his early life, that he was a soldier, married, and had several children, are fictitious. It is believed that he undertook a pilgrimage to the Holy Land, but did not reach Jerusalem. After the Council of Clermont in 1095 (See CRUSADE: URBAN II.) Peter appeared as a preacher of the Crusade in Northern and Central France. He rode on a mule, with a crucifix in his hand, his head and feet bare; his dress was a long robe and a hermit's cloak of the coarsest stuff, girt with a cord. He preached with the greatest earnestness in the pulpits, on the roads, and in the marketplaces, and everywhere aroused his hearers to a high pitch of enthusiasm, and was honored as a saint inspired from heaven. As early as April, 1096, Peter reached Cologne with a following of 15,000 men, and there his army received an accession of 15,000 more. They were mostly from the lower classes, poorly organized, and little fitted for war or the hardships before them. In dis-

[illegible] they made their way through Germany and Hungary toward Constantinople. (See CRUSADES.) Peter himself reached the city in July, 1096, accompanied his army across the Bosporus. But, disgusted by the insubordination of his followers, he returned to Constantinople and gave up the attempt to act as leader. During the siege of Antioch in 1098 he made a cowardly attempt to run away, but nevertheless was soon after trusted with a difficult commission to Kerbuga, King of Mosul, and acquitted himself with credit. During the winter of 1098-99, when many wished to abandon the Crusade, Peter appeared in his old rôle of preacher urging its continuance. He tried to defend the poor against the selfishness of the leaders. On the 8th of July, 1099, he preached on the Mount of Olives. After the capture of Jerusalem (July 15, 1099) he remained in the city, while the army proceeded toward Egypt. He returned home, probably shortly after the battle of Ascalon, and became monk and prior at Neufmoustier, near Huy, in the Diocese of Liège, where he died July 8, 1115. Consult, besides the general works on the Crusades, Hagenmeyer, *Peter der Eremit* (Leipzig, 1879); Franz, *Peter von Amiens* (Hofgeismar, 1891).

PETER THE VENERABLE (c.1094-1156). Abbot of Cluny. He was born at Montboissier, was educated in a Cistercian monastery, took the monastic vows in Cluny (1111), and was chosen prior of the famous monastery there when only twenty-eight years old. He cultivated learning and piety, and exemplified both in his own life. He visited England and Spain, and was in the Council of Pisa (1134). It is related that he reconciled the kings of Castile and Aragon, and that he advocated the claim of Innocent II. to the Papal throne, and secured his general acceptance by the Church. He also befriended Abélard, and gave him a refuge in the Monastery of Cluny for the close of his troubled life. Peter died at Cluny, December 25, 1156. Three of his treatises deserve separate mention: (1) *Against the Jews;* (2) *Two Books of Famous Miracles* (French trans. by d'Avenel, Paris, 1874); (3) *Against the Execrable Sect of the Saracens.* In the last work he shows considerable knowledge of his subject; he had a condensed Latin translation of the Koran made by his secretary, Peter of Poitiers, which was long the only one extant; it was edited by Bibliander and published at Basel in 1543. Unfortunately, only two of the five books of this treatise are extant. He also wrote against the Petrobrusians. (See BRUYS, PIERRE DE.) Peter's letters are important for the history of the period. His writings are collected in Migne, *Patrol. Lat.*, clxxxix. For his life, consult Wilkens (Leipzig, 1857) and D'Avenel (Paris, 1874).

PETER, APOCALYPSE OF. See APOCRYPHA, section on *New Testament*.

PETER, EPISTLES OF. Two of the seven so-called Catholic Epistles of the New Testament.

I. PETER. This document, according to its address, signature, and closing paragraph (i. 1-3 and v. 12-14), is a letter written by the Apostle Peter to the Christians of Asia Minor and sent thither by Silvanus, probably the Silas mentioned in Acts (xv. 22 onward). The Epistle was written to admonish and encourage those addressed to a cheerful, manly patience in persecution, to an orderly life, and to a steadfast hope. The doctrinal teachings are set forth incidentally to give the necessary foundation to the exhortations. The hortatory character of the Epistle makes it difficult to analyze satisfactorily. The following outline is suggested: After the usual address, signature and salutation (i. 1-2), the author fervently expresses his praise to God for the *Christian salvation*, the object and end of their sorely tried faith, foreshadowed in prophecy and now eagerly awaited (i. 3-12). This prepares for the three series of exhortations that follow. In the *first* (i. 13-ii. 10) the readers are exhorted to *earnestness, obedience*, and *holiness* with *godly fear* in view of the cost of their redemption (i. 13-21), to the exercise of brotherly love, as all of one divine regeneration (i. 22-25), and to a vital union with Christ, the chief corner stone (ii. 1-10). The *second* series (ii. 11-iv. 11) urges to orderly life (ii. 11-12), to all due subjection to constituted authority, even if suffering should ensue, citing the example of such suffering set by Christ (ii. 13-25); then passes to exhort wives to reverence their husbands (iii. 1-7), adding a general exhortation to all to be orderly, forbearing, and forgiving (iii. 8-12). In case this loyalty involves suffering, let them remember Christ's vicarious suffering and its blessed results, conform their conduct to His, and place their faith in Him, the risen Lord, especially since the end is near (iii. 13-iv. 11). The *third* set of exhortations (iv. 12-v. 11) pleads with those who are addressed not to take offense at the trials they are undergoing. If they are for loyalty to Christ, all is well. They must not suffer as evildoers (iv. 1-19). The church officers and members are urged to faithful performance of duties (v. 1-7), and the final exhortation to watchfulness is followed by a benediction (v. 8-11). The Epistle closes by stating that it is sent by Silvanus and with greetings from the church (or wife?) in 'Babylon' and from Mark. A short benediction is added (v. 12-14).

The doctrinal teachings of Peter, compared with those of the Pauline Epistles, are marked by a greater simplicity. They move within the sphere of Jewish-Christian thought and may be accounted for and explained on the basis of the application of the conviction that Jesus was the Messiah to the teachings of the Old Testament. The conception of God is that of the Old Testament, supplemented by the emphasis laid by Jesus on His Fatherhood (i. 3, 17). There is no distinctive Christology. Jesus is spoken of after the same manner as in the first chapters of Acts and in the Synoptic Gospels. The doctrine of redemption is fundamentally the same as that of Paul, but expressed differently, mainly in Old Testament language, and influenced largely by a deep appreciation of the human elements of Jesus' passion. The resurrection is the great fact that crowned the Messianic work of Jesus (i. 3, 11), and faith is fixed on that as well as on His death (iii. 22). The Christian life is founded on a vital union with the now living and glorified Jesus (i. 23-ii. 5). Salvation affects the real life, the 'soul' (i. 9 sqq.), and begins here through the new birth by the agency of the Word (i. 23). It becomes a possibility through *faith*, a word of broad significance in I. Peter, including the whole obedient response to the will

of God expressed in the life and work of Jesus the Messiah. The positive teachings concerning salvation reveal strong convictions concerning sin and its seat in man's being. The eschatology of I. Peter is simple. The future life is of far greater importance than this. We are only pilgrims here, and on that future we should fix our attention. It will be ushered in by a new revelation of Christ and will be an eternity full of glory (i. 7, 10; v. 10). The church organizations appear to have been simple. Elders are at the head and the younger element are urged to obey the older. As to baptism, not the form, but the heart condition is the important element (iii. 21).

The Epistle has been subjected to severe criticism. The central question is that of its genuineness. Is it what it purports to be? The external evidence in its favor is remarkably strong. All the prominent writers at the end of the second century, as well as Papias and Polycarp, early in the first century, used it as Peter's. No doubt as to its genuineness was expressed in the ancient Church.

The internal evidence in favor of Peter's authorship may be stated as follows: (1) The opening and closing sections, in which the writer calls himself the Apostle Peter, addresses a specific circle of Christian communities, states the name of the bearer of the Epistle (Silvanus), and sends greetings from Mark. Both Silvanus and Mark were fellow workers with the Apostles and members of the primitive Christian community of Jerusalem. If these sections state the truth, the genuineness of the Epistle must be admitted. If they are to be rejected as fictitious, strong grounds must be given for the rejection. (2) Incidentally, and without undue display, the writer represents himself as one who was an eye-witness of Jesus' ministry and passion (cf. i. 8, v. 1, and the warm-hearted way in which Jesus' sufferings are spoken of). (3) The independent character of the thought of the Epistle is, at least, not against its genuineness. The brief sketch of the teachings of the Epistle given above reveals this. While the writer comes close to Paul's language at times, he is no mere echo of Paul, nor is he a blundering copyist. (4) There is a genuine and serious tone and purpose to the Epistle, exhorting its readers to all that is good, which makes it difficult to account for as a forgery.

The main objections to Petrine authorship based on internal evidence are: (1) The trials or persecutions referred to imply a date later than the end of Peter's life. In regard to this it may be said that the statements in the Epistle do not imply a regularly organized *State* persecution of Christians as such. The general opposition of the pagan world and of the Jewish element are sufficient to account for all that is said. That this opposition was severe in Apostolic days the letters of Paul and the record in Acts abundantly testify. It is not necessary to presuppose even the persecution of Nero as implied in the Epistle. Such a passage as ii. 13 sqq. does not point that way. (2) The Epistle is said to manifest great dependence on Paul's writings, which, it is thought, militates strongly against Petrine authorship. In regard to this it may be replied: (a) There is no inherent impossibility in the supposition that Peter may have known and valued Paul's writings and used expressions from them in a writing of his own. (b) It is probable that a literary relationship exists between our Epistle and Romans and Ephesians. But it may be, as Weiss and Kühl claim, that Paul is here dependent on I. Peter. (c) In any case the author of I. Peter is master of his own thought and language. In this short Epistle he uses at least sixty words not found elsewhere in the New Testament, and gives to many common words a special, peculiar sense. (3) The Greek of I. Peter, though not so good as that of II. Peter, is said to be of a quality far beyond the capability of Peter, an ignorant Galilean fisherman. But the fact is, we know nothing of Peter's knowledge of Greek. That language was largely spoken in Galilee, and Peter may have gained some proficiency in it. He may, however, have used Mark or Silvanus to write the Epistle, dictating the matter in Aramaic and leaving the writer to put it into popular Greek. Other objections hold against certain theories regarding the date, place of writing, and class of Christians addressed, but not against the Epistle *per se*.

We may affirm, then, that the general character of the Epistle and its history in the Church are not opposed to its own claim to be an epistle of the Apostle Peter. It only remains to consider the questions of destination and date. The plain, literal sense of the words, "to the elect sojourners of the dispersion," etc., indicates *Jewish*-Christian communities in the various provinces of Asia Minor as the parties addressed. The main objections to this view are that, according to Acts and Paul's Epistles, the Christianity of Asia Minor was overwhelmingly *Gentile*-Christian, and that no epistle addressed to Jewish-Christians would have used such language as we find in i. 18 and iv. 3-4. These objections are strong, though not conclusive. The work of Paul covered half of the territory indicated in the address, and many Jewish-Christian workers may have labored in Northeastern Asia Minor and even in the regions traversed by Paul. The second objection is more serious, but it cannot be said that Peter could not have used such language in addressing churches which, though composed mostly of Jewish-Christians, still contained some converts from paganism.

It is possible, however, to take the word 'dispersion' in a figurative sense and consider that the Epistle was addressed to Christians as such, whether of Jewish or pagan ancestry. In some parts of Asia Minor the former may have predominated; in other parts, especially in the western districts, the latter. It was only natural that the Apostle, himself a Jewish-Christian whose experience had been mainly with Jewish-Christians, should address them all as the true Israel. Since Paul had evangelized only a part of Asia Minor, an epistle addressed to churches scattered through the whole vast province had no occasion to mention him. It is probable that by 'Babylon' (v. 13) Rome is intended. Whether the term 'fellow elect' (fem.) means the Church or some individual (the writer's wife?) is a question.

The date to be assigned to the Epistle depends mainly on the answers to two questions: (1) To what do the references to suffering point? If nothing less than a State persecution is implied, the time of the persecution by Nero is the earliest possible date—i.e. c.64 A.D. If no State persecution is implied, the Epistle may well have

been [illegible]r. (2) The question of the relation between Peter and the Pauline Epistles. If I. Peter is dependent on Romans and Ephesians, it must be dated either after Paul's first imprisonment, i.e. after 61, while Paul was away from Rome, or during that imprisonment, while Paul also was in the city. Most critics who hold to the genuineness of the Epistle and to its dependence on Paul are inclined to a date near 64 A.D. Ramsay (*The Church in the Roman Empire*, pp. 279-295, Oxford, 1893) advocates 80 A.D. Those who dispute Peter's authorship assign different later dates. But if the dependence is on the side of Paul rather than Peter, the Epistle was written before Romans. This opinion, advocated by Weiss and Kühl, has much in its favor, and appears, on the whole, the most probable. Accordingly the Epistle may be viewed as written at Rome some time between 50 and 55 A.D.

II. Peter. This Epistle purports to be from the Apostle Simon Peter to (an unnamed circle of) Christians. After exhorting them to fulfill their high destiny by a complete, well-developed Christian life (i. 3-11), he declares his purpose ever to remind them of these things, especially as he knows that his death is near, and is certain of the truth of the doctrines of the power and Second Coming of Christ (see Second Advent of Christ), both from his own experience at the Transfiguration, and from the more sure word of prophecy (i. 12-21). He then passes to his main theme, warning against the threatened inroads of false teaching represented by bold, irreverent, reckless Antinomianism and by a skeptical denial of the Second Coming (ii. 1-iii. 13). The Epistle closes with a reference to Paul as teaching the same truths, though often misunderstood, and by an exhortation to constant Christian growth (iii. 14-18).

Unlike I. Peter, this Epistle seems to have been called forth by some very urgent conditions in certain Christian communities. Its scope is not so broad nor its teachings so diversified as is the case with I. Peter. Only in the very condensed passage i. 3-11 is a comparison between the two Epistles possible.

Because of its somewhat unique character, II. Peter has proved an inviting field for biblical criticism, and the questions of its authorship, date, and destination are still open. The external attestation to the Epistle is probably weaker than in the case of any other New Testament writing. There is no distinct trace of its existence before Origen, though it is probable that it was commented on by Clement of Alexandria (c.190). We must then be content with such evidence as the Epistle itself offers. Petrine authorship is, without doubt, claimed, not only in the opening words, but in the reference to the Apostle's death, as revealed by the Lord (i. 14), in the reference to the Transfiguration (i. 16), and in the notice of Paul's letters (iii. 15). Nevertheless, grave objections may be made against this claim. Arguments drawn from the vocabulary and style of the Epistle are not of great weight, because of our imperfect knowledge of Peter's habits and circumstances. The remarkable, almost verbal similarity between II. Peter ii. 1-iii. 3 and the short Epistle of Jude demands explanation. If, with most modern scholars, we hold that this section of the Epistle was copied from Jude, it becomes very difficult to maintain the Apostolic authorship of II. Peter, not only on general grounds, but also because the errorists combated are spoken of in Jude as already in the community, while in the Epistle their appearance is still future, or at least indicated as very recent. It is much simpler, and more in accordance with the statements of both Epistles, to hold that Jude used II. Peter. If such be the case, Jude is additional evidence for the early date of the Epistle. Arguments based on the marked dissimilarity between I. and II. Peter are of force only as against the view that both Epistles were written near the same date by Peter's own hand, or by the same amanuensis and to the same circle of readers. No one of these suppositions, however, is necessary. The relation between II. Peter and apocryphal writings of Josephus is too uncertain for a basis of argument.

While conceding the great weight of opposing theories and the complicated and uncertain character of the evidence, the most probable view seems to be that the Epistle was written near the close of Peter's life, presumably from Rome, to Jewish-Christian readers, well known to the Apostle, who were threatened with the invasion of new and dangerous heresy. It had a limited circulation, but became known some years later to Jude, who used it as the basis for his hastily written Epistle to the same or nearly related communities.

Bibliography. The recent and able commentaries by Kühl, in Weiss's series (Göttingen, 1897); Bigg, International Critical Series (New York, 1901); and Von Soden, in the Holtzmann Series (Leipzig, 1899), are full and leave little to be desired. Chase, in the Hastings *Dictionary of the Bible*, gives an exhaustive treatment with a good bibliography. For the theology of I. Peter, consult the standard New Testament theologies of Weiss, Beyschlag, Holtzmann, Stevens, and also Weiss, *Der petrinische Lehrbegriff* (Berlin, 1855). The various introductions to the New Testament, and works on the Apostolic Age contain full discussions of the critical problems. For II. Peter consult also Spitta, *Der zweite Brief des Petrus und der Brief des Judas* (Halle, 1885).

PETER, Gospel of. See Apocrypha, section on *New Testament*.

PETER, Preaching of. See Apocrypha, section on *New Testament*.

PETER, pā'tēr, Hermann (1837—). A German classical scholar, son of the following, best known for his work in Roman history. He was born at Meiningen, studied at Bonn and Breslau, taught at Posen, Frankfort-on-the-Oder, and Meissen, and in the last place became rector of the school. His works include important editions of *Scriptores Historiæ Augustæ* (1865; 2d ed. 1884; and critical essays on the same subject, 1892); *Historicorum Romanorum Reliquiæ* (1870); and *Historicorum Romanorum Fragmenta* (1883), as well as Ovid's *Fasti* (1874; 3d ed., 1899); and the critical essays, *Die Quellen Plutarchs in den Biographien der Römer* (1865), and *Die geschichtliche Litteratur über die römische Kaiserzeit bis Theodosius I. und ihre Quellen* (1897).

PETER, Karl Ludwig (1808-93). A German historian and classical scholar. He was born at Freiburg and studied at Halle. For several years he served as professor of history in the University of Jena. His writings include: *Die*

Epochen der Verfassungsgeschichte der römischen Republik (1841); *Geschichte Roms* (4th ed. 1881); *Studien zur römischen Geschichte* (1863); and *Zur Kritik der Quellen der ältern römischen Geschichte* (1879).

PETER BELL. A tale in verse by William Wordsworth (1819) of a man in humble life, with incidents of such exaggerated simplicity as to provoke much ridicule.

PE'TERBOROUGH. An episcopal city, a Parliamentary and municipal borough, and a civic county, known as the soke or liberty of Peterborough, in Northamptonshire, England, on the Nen, 37 miles northeast of Northampton, and 76 miles north by west of London (Map: England, F 4). Its principal edifice is the famous cathedral, which has undergone complete restoration since 1883, and holds a high rank among English cathedrals of the second class, exhibiting all grades of transitional architecture from Norman to Perpendicular. The south transeptal crypt incloses the site of the prior cruciform Saxon church. The west front as a portico is said to be the finest in Europe. A central tower, lantern-shaped, rises at the intersection of the nave and transept. The length of the cathedral is 476 feet; breadth at the great transepts, 203 feet; height of central tower from the ground, 150 feet. The town is regularly laid out, has an excellent grammar school with an endowment, a public library, a school of art, science, and technology, a corn exchange in the Italian style, a jail and house of correction, a handsome parish church, and a number of charitable institutions. The city owns its water and electric lighting works, markets, sewage farm, bathing place, and isolation hospital, maintains parks and recreation grounds, and provides cottage allotments. Peterborough is an important railway centre and carries on an active trade in corn, coal, timber, bricks, and malt. It has also manufactures of agricultural implements and extensive locomotive works.

Anciently named Medeshamstede, the city had its origin in a great Benedictine monastery, founded in 655. This monastery, reared in honor of Saint Peter, became one of the wealthiest and most important in England, but it was not until after having been destroyed by the Danes in 807, and rebuilt about 966, that the town was called Peterborough. On the dissolution of the monasteries, the magnificent cathedral was spared, owing, it is supposed, to its containing the remains of Queen Catharine of Aragon, but it was vandalized by Cromwell and his troopers in 1643. Population, in 1801, 3400; in 1851, 8700; in 1881, 21,228; in 1901, 30,870. Consult: Poole, *Peterborough* (London, 1881); Davys, *The Cathedral and Abbey of Peterborough* (Peterborough, 1886); Sweeting, *Peterborough Cathedral* (London, 1898).

PETERBOROUGH. The capital of Peterborough County, Ontario, Canada; on both sides of the Otonabee River and on the Canadian Pacific and the Grand Trunk railroads, 76 miles northeast of Toronto (Map: Ontario, E 3). It is connected by a handsome bridge with the village of Ashburnham opposite. The town is lighted with gas, has good water power, manufactures leather, engines, farming tools, wooden ware, and woolens, and carries on a large export trade in grain, pork, and lumber. It is the seat of a United States consular agent. The town is the centre of a picturesque lake and river district, and is a favorite resort for sportsmen; the Peterborough or Rice Lake canoe was invented here. Population, in 1891, 9717; in 1901, 11,239.

PETERBOROUGH, CHARLES MORDAUNT, third Earl of (1658-1735). An English military and naval commander. He served as a boy in the navy, and then entered the army. For the prominent part that he took against James II., he was made Earl of Monmouth by William III., succeeding afterwards to the earldom of Peterborough, as heir to his uncle. During the War of the Spanish Succession the English expedition to the Iberian Peninsula was placed under his command, and in June, 1705, he arrived in Lisbon with 5000 Dutch and English soldiers. After taking on board the Archduke Charles of Austria, who claimed the Spanish crown, the armament proceeded to Valencia. Mordaunt conceived the idea of making a dash at Madrid, and finishing the war at one blow, but was overruled by the Archduke and the Prince of Hesse, and compelled to besiege Barcelona, which was defended on one side by the sea, and on the other by the strong fortifications of Monjuich. By a *coup de main* he made himself master of Monjuich, Barcelona fell, and Mordaunt pushed his successes into the interior. Several towns submitted. He marched to Valencia and at the head of 4200 men defeated a Spanish force of 4000. The Spaniards sent a large army into Catalonia, and a French fleet appeared off Barcelona. Mordaunt returned to Barcelona, harassed the enemy's army, and, putting himself on board the English squadron, directed a movement which compelled the Frenchmen to put to sea, and Barcelona was saved. Mordaunt again wished to march toward Madrid, but his plan for gaining possession of the capital was once more rejected by Charles. He accordingly left the army in a fit of pique, and went to Italy. In 1707 he returned to Valencia as a volunteer, but the excellent advice which he gave was not followed. He was recalled to England, and from that moment the tide of fortune ran strong against the Austrian cause. On his return he made common cause with the Tories, and received the Garter and other dignities for his services. On the accession of George I. he was appointed commander-in-chief of the naval forces of Great Britain. He died at Lisbon. Brilliant and versatile, he was also eccentric and erratic. His witty yet affectionate letters to Pope, Swift, Prior, etc., give a fine insight into his private character. His character has been sketched by Horace Walpole, in his *Catalogue of Royal and Noble Authors*, and with still greater force and picturesqueness by Macaulay. Attempts have been made to discount the brilliancy of his leadership in the Spanish campaign and to attribute the successes to other officers, but these have signally failed. Consult: Warburton, *Memoirs of Charles Mordaunt, Earl of Peterborough and Monmouth* (London, 1853); Russell, *Memoir of Charles Mordaunt, Earl of Peterborough* (ib., 1887); Stebbing, "Peterborough," in *English Men of Action* (ib., 1890).

PE'TER CLA'VER, SAINT (1580-1654). The apostle of the negroes in Spanish America. He was born in Catalonia of a noble family. After completing his education in the Jesuit college at Barcelona, he joined the novitiate of the Society at Tarragona in 1602, and

was [illegible] the newly founded college at Montrege. While he was still pursuing his studies, the general, Aquaviva, called for an approved missionary from each Spanish province of the society to go to the newly formed province of Granada in South America. Peter Claver was among those chosen, and arrived at Cartagena, then the centre of the African slave-trade, in 1610. In 1616 he was ordained, and entered on his special work. He won the approval of the authorities for his plan, and secured orders that no slave-owners should be allowed to carry off the newly imported blacks until they had had instruction in the Christian faith. He signed himself the 'slave of the negroes forever,' and practically lived among them, on shipboard and in the hospitals, especially the leprosy hospital, ministering to their wants, as well temporal as spiritual. His exertions during the plague in Cartagena resulted in utter exhaustion and paralysis, and he died September 8, 1654. He was beatified by Pius IX. in 1852, and canonized by Leo XIII. in 1888. Consult his *Life* by Fleuriau (Eng. trans. London, 1847) and Höver (Düllmen, 1888).

PETER DE VIN'EA (c.1190-1249). An Italian statesman and jurist, born at Capua. By his abilities he attracted the attention of Emperor Frederick II., and as early as 1225 he appears as occupying a high judicial position in Frederick's kingdom of Sicily. He soon became the chief judicial officer in the realm, and aided in drawing up the Constitution of 1231 for Sicily, which was far in advance of any other instrument of government of Western Europe at that period. After filling other very high offices, Peter was suddenly arrested on suspicion of having been bribed to poison the Emperor. It is said that, in order to avoid torture and further disgrace, he dashed out his brains against a pillar, to which he had been chained. Dante has sought to clear his good name, and many beautiful legends arose concerning the tragic fate of the great statesman. His letters, poems, and speeches form one of the most useful sources for the history of his time. Consult: Huillard-Bréholles, *Vie et correspondance de Pierre de la Vigne* (Paris, 1865); Kington, *History of Frederick II.* (London, 1862).

PE'TERHEAD. A seaport and Parliamentary burgh in the District of Buchan, Aberdeenshire, on a peninsula, the easternmost point of land in Scotland, 14 miles northeast of Aberdeen (Map: Scotland, G 2). Keith Inch, the eastern head of the peninsula and the nucleus of the town, mainly occupied by fish-curing establishments, is now separated by a canal which connects the five spacious harbors. The town is irregularly built, clean, and paved with the reddish granite named after the town, but has no striking edifices. The parish church has a granite spire, 118 feet high, and a granite Tuscan pillar stands on the market-cross. There are Episcopal, Free, Roman Catholic, and other churches; an academy and other schools, and libraries. The town owns its water supply, winter and summer baths, and a municipal lodging house. Formerly the chief British depot of the whale and seal fisheries, it is now noted for its herring fishery, employing over 500 boats and 5000 persons. The general trade is of considerable importance. The chief exports are herrings, cattle, agricultural produce, and granite. Granite and polishing works, ship and boat building, woolen factories, and breweries are carried on. Peterhead dates from the thirteenth century. The Pretender landed here on December 25, 1715. Population, in 1891, 12,200; in 1901, 11,750.

PETERHOF, pā'tĕr-hŏf. A town in the Government of Saint Petersburg, Russia, situated on the Gulf of Finland, 18 miles west of the capital (Map: Russia, D 3). It is a well laid-out town, occupied chiefly by fine villas and summer residences which extend along the gulf to Oranienbaum on the west and Saint Petersburg on the east. The royal palace, with its extensive gardens, fountains, and statues modeled after those at Versailles, was begun by Peter I. in 1711, and has since been greatly extended and embellished by the successive monarchs, especially by Elizabeth, Catharine II., and Nicholas I. It contains many rare works of art. Peterhof is now one of the most fashionable resorts around the capital, and the Russian Court usually spends there a part of the summer. Population, in 1897, 11,300.

PE'TER IB'BETSON. A novel by George Du Maurier (1891). It appeared serially in *Harper's Magazine* of that year. The story opens with Peter's childhood in Paris, and his playmate, Mimsey Seraskier. Left an orphan, he is brought up by a disagreeable uncle. He meets Mary, the charming Duchess of Towers, and discovers in a dream that she is Mimsey. Exasperated by his uncle, Peter kills him in a sudden frenzy, and for twenty-five years in prison he leads a dream life in which he has mysterious communication with the Duchess. At her death he becomes insane; she comes to him once afterwards and influences him to write this curious autobiography.

PETER LOMBARD, or PETER THE LOMBARD (c.1100-64). An Italian theologian. He was probably born at Lumello, in Lombardy, about the year 1100. He studied at Bologna, Rheims, and later at Paris, where he was a pupil of Abélard. He became teacher of theology in the cathedral school of Notre Dame, and in 1159 was appointed bishop of Paris. He resigned the see after a year and died at Paris, July 20, 1164. He was very generally styled *Magister Sententiarum*, or *Master of the Sentences*, from his compilation *Sententiarum Libri IV.*, a collection of sentences from Augustine and other Fathers on points of Christian doctrine, with objections and replies also collected from authors of repute. It was intended as a manual for the scholastic disputants of his age, and as such was used for 500 years and made the basis of innumerable lectures and treatises. It was one of the first books printed, and many editions have been issued. It is found in Migne, *Pat. Lat.*, vols. cxci-cxii., with his *Catena* on the Psalms and on Paul's Epistles. Consult the treatise of Protois, *Pierre Lombard, son époque, sa vie, ses écrits, son influence* (Paris, 1881).

PE'TERLOO MASSACRE (fanciful name, suggested by *Waterloo*). The name popularly given to the dispersal of a large meeting by armed force in Saint Peter's field, Manchester, England, Monday, July 16, 1819. The assemblage, consisting chiefly of bodies of operatives from different parts of Lancashire, was called to consider the question of Parliamentary reform. The dispersal took place by order of the magistrates. Eleven persons were killed and more than 500 wounded.

PETERMANN, pā'tĕr-mân, AUGUST (1822-78). A German geographer. He was born at Bleicherode, in Prussian Saxony; studied at Nordhausen; and from 1839 to 1845 was an assistant in the geographical academy of Professor Berghaus at Potsdam. There he worked upon Berghaus's *Physikalischer Atlas*, and drew the map for Alexander von Humboldt's *Asie Centrale*. In 1845 he went to Edinburgh as assistant to A. K. Johnston in the preparation of his *Physical Atlas*, based upon the publication of Berghaus. In 1847 Petermann founded a cartographic establishment at London, and was elected to the Royal Geographical Society. He then made a special study of the geography of Africa and of the Arctic Zone. In 1854 he returned to Germany to assume the directorship of Justus Perthes's geographic institution at Gotha, and in 1855 founded the *Mittheilungen*, a monthly geographical journal, which remains the authoritative publication in its particular department. Like his father and his brother before him, he died by suicide.

PETERMANN, JULIUS HEINRICH (1801-76). A German Oriental scholar. He was born at Glauchau, was educated at Leipzig and Berlin, and studied Armenian at Venice. In 1837 he became professor of Oriental languages at the University of Berlin. From 1852 to 1855 he traveled through Asia Minor and Persia; in 1867-68 through Palestine and Syria; during the latter year he was German consul at Jerusalem. Petermann published grammars of the Samaritan, Aramaic, and Armenian languages in the *Porta Linguarum Orientalium* series. Among his other works are *Reisen im Orient* (1860-61), and an edition of the *Samaritan Pentateuch* (1872 seq.), continued after his death by Vollers.

PETER MARTYR. The name most commonly applied to PIETRO MARTIRE DI ANGHIERA (c.1457-1526), an Italian writer on American history. He was born at Arona, in Northern Italy, probably on February 2, 1457, although his own letters give almost equally good grounds for the years 1455 and 1459 as the date of his birth. In 1477 he went to Rome, where, through the Cardinal Ascanio Sforza, he secured the position of secretary to Francesco Negro, the Governor of the city, which he held until August, 1487, when he was induced to go to Spain by the retiring Spanish Ambassador, the Count of Tendilla. There he seems to have quickly become a chronicler, and in this capacity he came under the immediate protection of the Queen. In 1494 he was ordained as a priest and became tutor to the children of Ferdinand and Isabella. In 1501 he was intrusted with a diplomatic mission to the Sultan of Egypt, who had threatened to massacre all Christians in his domains in revenge for the expulsion of the Moors from Spain. Martyr's account of his successful visit to Cairo is narrated in his *Legatio Babulonica*, which he dedicated to Pope Leo X. In reward, he received an appointment as apostolic prothonotary. In 1505 he also obtained the post of dean of the chapter of the Cathedral of Granada, which he held until his death. In 1520 he was appointed royal chronicler or historiographer, and subsequently a member of the Council for the Indies. His principal works are the history of the New World, *De Rebus Oceanicis et Novo Orbe Decades*, and the *Opus Epistolarum*. The *Decades* constitute an important source for the early period of American discovery. The *Opus* is an invaluable collection of 816 letters dealing with contemporary events. Consult: Mariéjol, *Pierre Martyr d'Anghiera, un lettré italien a la cour d'Espagne* (Paris, 1887); Bernays, *Petrus Martyr Anglerius* (Strassburg, 1891); Thacher, *Christopher Columbus* (New York, 1903).

PETER MARTYR. A sixteenth century religious reformer. See VERMIGLI.

PETERS, pā'tĕrs, CHRISTIAN AUGUST FRIEDRICH (1806-80). A German astronomer, born in Hamburg. He studied at Königsberg, was employed in the Altona Observatory, and in 1839 was appointed assistant at Pulkova. Ten years after, Peters became professor at Königsberg, and in 1854 was appointed director of the Observatory at Altona, and undertook the editorship of *Astronomische Nachrichten*. He went to Kiel in 1872, when the Observatory was transferred thither, and in 1873 he was chosen professor of astronomy in the university of that place. His work was almost entirely on stellar astronomy and dealt especially with stellar parallaxes, the constant of nutation, and the study of Sirius.

PE'TERS, CHRISTIAN HEINRICH FRIEDRICH (1813-90). A German-American astronomer, born at Koldenbüttel, in Schleswig. He studied in Berlin; worked in the observatories of Copenhagen and Göttingen, then under Sartorius von Waltershausen in the survey of Etna, and in the topographic bureau of Naples; and in 1854 came to the United States. For several years he was employed on the coast survey, and in 1858 was appointed professor of astronomy at Hamilton College, and director of the Litchfield Observatory. His greatest services to astronomy were the discovery of about fifty comets and planetoids, and the stellar charts published in 1882. Peters led the United States expedition to New Zealand for the observation of the transit of Venus in 1874.

PETERS, or **PETER**, HUGH (1598-1660). An English churchman and author. He was educated at Cambridge, was ordained, and preached at the Church of Saint Sepulchre, London, until he was silenced for non-conformity; he went to Rotterdam, and became pastor of the Independent Church. He was in New England from the winter of 1635-36 to 1641; was settled pastor of the First Church in Salem, Mass., as successor of Roger Williams. As chaplain in the Parliamentary army he rendered unusual services, for which he was rewarded under the Commonwealth and the Protectorate. After the Restoration, being suspected of complicity in the King's death, he was indicted for high treason, condemned, and beheaded, October 16, 1660. During his imprisonment he addressed to his daughter, Elizabeth, *A Dying Father's Last Legacy to an Only Child*. He published *Peters's Last Report of the English Wars* (1646); *A Word for the Army and Two Words for the Kingdom* (1647); *A Good Work for a Good Magistrate* (1651); and several other pamphlets. Consult Felt, *Memoir and Defense of Hugh Peters* (Boston, 1851).

PETERS, JOHN CHARLES (1819-93). An American physician; born in New York; studied medicine in Columbia and in Europe, and commenced practice in New York as a homœopathist, but afterwards joined the regular school. He published treatises on diseases of the head, of

[illegible] of the eyes, and Asiatic cholera. In collaboration with Dr. E. F. Snelling and others, he published a *Materia Medica*. Dr. Peters was editor of the *North American Journal of Homœopathy*, and of the *Transactions* of the Pathological Society.

PETERS, John Punnett (1852—). An American clergyman and Orientalist, born in New York City. He graduated at Yale (1873), and studied at Berlin and at Leipzig. He became professor of Old Testament languages and literature at the Protestant Episcopal Divinity School in Philadelphia (1884) and professor of Hebrew at the University of Pennsylvania (1885), and from 1888 to 1891 conducted excavations at Nippur. In 1893 he became rector of Saint Michael's Church, New York City. He wrote: *Scriptures, Hebrew and Christian* (1886-89); *Nippur, or Explorations and Adventures on the Euphrates* (1897); and *The Old Testament and the New Scholarship* (1901).

PETERS, pā'tĕrs, Karl (1856—). A German traveler. He was born at Neuhaus, in Hanover, and studied at Göttingen, Tübingen, and Berlin, where in 1880 he became privat-docent. In 1884 he founded the German Colonization Society, in whose interests he traveled through Eastern Africa. Returning to Germany in 1885, he became the head of the German East African Company, and two years later went again to Africa to assume the management of the colonial possessions. In 1888 he took the leadership of an expedition for the relief of Emin Pasha, marched up the Tana River to its source, and penetrated finally to the Victoria Nyanza. He crossed the lake in June, 1890, met Emin, already rescued by Stanley, and thence returned to the coast. In February, 1891, he was sent as Imperial commissioner to East Africa; founded a station at Kilimanjaro, and was active in the settlement of the boundary between German and English possessions. Accusations of cruelty toward the natives were in 1896 preferred against him. They were investigated before a judicial commission, and resulted in his dismissal from the service. In 1898 he went to London and formed a company for the exploration of the gold-fields of Rhodesia, and he himself visited Africa again in 1900-01. His publications include: *Willenswelt und Weltwille* (1883), a philosophical study; *Die deutsche Emin Pascha-Expedition* (1891); *Das deutsch-ostafrikanische Schutzgebiet* (1895); *Das goldene Ophir Salomos* (1895); and *Aequatorial und Südafrika nach einer Darstellung von 1719* (1895).

PE'TERS, Madison Clinton (1859—). An American clergyman, born in Lehigh County, Pa. He was educated at Franklin and Marshall College, and at Heidelberg Theological Seminary, Tiffin, Ohio, whence he entered the ministry of the Reformed Church, becoming pastor of the Bloomingdale Congregation in New York City. After a pastorate of eleven years he resigned, joined the Baptist Church, and became pastor of the Sumner Avenue Baptist Church, Brooklyn, N. Y. He defended this change of denomination in *Why I Became a Baptist* (1901). Among his other works are: *Justice to the Jew* (1899); *The Wit and Wisdom of the Talmud* (1900); *The Birds of the Bible* (1901); *The Jew as a Patriot* (1902); and several devotional books.

PETERS, Phillis. The name, after marriage, of the colored poet Phillis Wheatley (q.v.).

PETERS, Richard (1744-1828). An American jurist, born in Belmont, Pa. (now part of Philadelphia). He graduated at Philadelphia College (now University of Philadelphia) in 1761, studied law, and soon rose to eminence at the bar. During the Revolutionary War he was captain of a militia company in 1775-76, was secretary of the Board of War from 1776 to 1781, and was instrumental in having Benedict Arnold tried before a court-martial in January, 1780. He was a member of Congress in 1782-83, sat in the State Assembly in 1787-91, and was a United States district judge from 1792 to 1828. He was one of the founders of the Philadelphia Agricultural Society and its president for more than thirty years, wrote many valuable papers on agricultural subjects, and in 1797 demonstrated by a series of experiments the agricultural value of gypsum. He published *Admiralty Decisions in the United States District Court of Pennsylvania* (2 vols., 1807). His son, Richard Peters, Jr. (1780-1848), was successor of Henry Wheaton as reporter of the United States Superior Court, and published *Reports of the United States Circuit Court, 1803-18* (1819); *Reports of the United States Supreme Court, 1828-43* (17 vols., 1828-43); *Condensed Reports of Cases in the United States Supreme Court from Its Organization till 1827* (6 vols., 1835); and *Case of the Cherokee Nation Against the State of Georgia*. He was also editor of *Chitty on Bills;* Bushrod Washington's *Circuit Court Reports, Third Circuit* (4 vols., 1803-27); and of the *United States Statutes at Large*.

PETERS, Samuel (1735-1826). An American clergyman, the author of a well-known history of Connecticut. He was born in Hebron, Conn., graduated at Yale in 1757, and in 1759 was ordained in London as a minister of the Church of England. Returning to Connecticut in 1760, he was placed in charge of the churches of Hebron and Hartford. In the pre-Revolutionary controversies he embraced the Tory cause, and was so pronounced in his loyalty to the Crown that in 1774 he was forced by the 'Sons of Liberty' to abandon the colony and take refuge in England. Here in 1781 he published anonymously his celebrated *General History of Connecticut, from Its First Settlement Under General Fenwyck, Esq., to Its Latest Period of Amity with Great Britain* (republished in New York, 1877), in which he gave a code of so-called 'blue laws' which attracted widespread attention. These laws were formerly supposed to have been pure forgeries and fabrications, but recent investigations have shown them to have been taken in part from an earlier writer (Neal) and in part (with modifications) from actual laws, only two or three of the forty-five having been apparently invented out of hand. In 1805 Peters came to New York. In 1817 he visited the Falls of Saint Anthony, taking up a large claim there, but again settled in New York (1818) and died there in great poverty eight years later. He published a number of books and pamphlets, characterized by a slovenly and uncritical scholarship, and by a general uniformity of misstatement and reckless assertion. Consult: Trumbull, *The Rev. Samuel Peters, His Defenders and Apologists* (Hartford, 1877); id., *The True Blue Laws of Connecticut and New*

Haven (Hartford, 1876); and "Examination of Peters's Blue Laws," by Prince, in *Annual Report of the American Historical Association* for 1898.

PE'TERSBURG. A city and the county-seat of Menard County, Ill., 20 miles northwest of Springfield; on the Sangamon River, and at the junction of the Chicago, Peoria and Saint Louis and the Chicago and Alton railroads (Map: Illinois, C 4). It is surrounded by a farming and stock-raising district, having deposits of coal. There are several coal mines and various manufactories, including flouring mills, a canning factory, brick and tile plant, etc. Population, in 1890, 2342; in 1900, 2807.

PETERSBURG. A town and the county-seat of Pike County, Ind., 44 miles north by east of Evansville; on the Evansville and Terre Haute Railroad (Map: Indiana, B 1). It has manufactures of flour, brick and tile, lumber, etc., and considerable trade in coal, which is mined extensively in the vicinity. Agriculture and stock-raising also are important industries in the fertile region adjacent. Natural gas is found here. Population, in 1890, 1494; in 1900, 1751.

PETERSBURG. A city, independent of county authority, at the junction of Chesterfield, Dinwiddie, and Prince George counties, Va., 22 miles south of Richmond, on the Appomattox River and the upper Appomattox Canal, and on the Norfolk & Western, the Atlantic Coast Line, and the Seaboard Air Line railroads (Map: Virginia, G 4). There are two steel bridges across the river, and two public parks. Petersburg is the seat of the State Central Hospital for the Insane, with 1000 colored patients; the Virginia Normal and Collegiate Institute, for the higher education of colored students of both sexes; Southern Female College; and the University School for young men. It has a Benevolent Mechanics' Association, with a library and museum. There are also the Young Men's Christian Association; the Home for the Sick; and fine Masonic, Odd Fellows', and Red Men's buildings. Petersburg carries on an extensive trade in tobacco, and is an important industrial centre, its manufacturing interests being promoted by excellent water power. The products of the principal industries are cotton, tobacco, machinery, trunks, clothing, silk and knit goods. Under a charter of 1875, the government is vested in a mayor, elected every two years, and a council which controls elections of all officials governing the administrative departments. The water works are owned and operated by the municipality. Population, in 1890, 22,680; in 1900, 21,810.

Petersburg was founded in 1733 on the site of an Appomattox Indian village destroyed in 1676 by Nathaniel Bacon; was incorporated as a town in 1748, and was chartered as a city in 1850. During the Revolution it was twice occupied by the British under General Philips, and in the War of 1812 the Petersburg volunteers served with conspicuous gallantry. Being a great railway centre of supply from the south, Petersburg was the scene of much of the fighting in the famous Virginia campaign of 1864-65. (See CIVIL WAR.) After his disastrous failure at Cold Harbor June 3, 1864 (q.v.), Grant marched his army of more than 100,000 men to the James River, with the idea in part of taking Petersburg and thus of forcing the evacuation of Richmond. General Butler, at Bermuda Hundred, was hastily reinforced by a corps under General W. F. Smith, and was ordered to attack Petersburg, then defended by only 2500 Confederates. But though his force numbered 16,000, he carried out his orders (June 15th) half-heartedly and inefficiently and thus allowed Confederate reinforcements to be thrown into the city. Grant, arriving on June 16th, made bloody but unsuccessful assaults on the 16th, 17th, and 18th, his losses for the three days being fully 10,000. He then settled down for a siege. On July 30th the famous Petersburg mine—a shaft 520 feet long with lateral branches (near the end) extending 40 feet on each side—was exploded with terrific effect, a Confederate regiment being destroyed and a huge crater produced, through which an inefficiently commanded force of Federals tried to fight its way. The Confederates quickly recovered, poured a deadly artillery fire into the crater, and the Federals were forced back with a loss of more than 4000. Lee repeatedly foiled the manœuvres of Grant, but finally, on April 2, 1865, after the disaster at Five Forks, was compelled to evacuate both Petersburg and Richmond. Consult Humphrey, *The Virginia Campaign of 1864 and 1865* (New York, 1883).

PETER SCHLEMIHL, pā'tĕr shlā-mēl'. A widely popular tale by Chamisso (1813), relating the adventures of a man who sells his shadow to the Evil One in return for an inexhaustible magic purse. His wealth, however, does not save him from the suspicion and horror with which his fellows regard his strange condition. He is unwilling to buy back his shadow at the stipulated price, his soul, and in despair throws away the purse, buying with his last money a pair of seven-league boots. With these he traverses the whole earth and by his study and knowledge of the world at last gains contentment.

PETERSEN, pā'tĕr-sen, EUGEN (1836—). A German archæologist, born at Heiligenhafen, in Holstein. He studied at Kiel and Bonn, in 1873 was appointed professor of archæology at Dorpat, and in 1879 at Prague. He was a member of the Austrian archæological expeditions to Greece in 1880 and to Asia Minor in 1882-85. In 1886, after removing to Berlin, Petersen was sent to Athens as secretary of the German Archæological School, and in 1887 was transferred to a corresponding post in the German School at Rome. He edited Theophrastus's *Characters* (1859), and wrote: *Die Kunst des Pheidias am Parthenon und zu Olympia* (1873); *Reisen in Lykien* (with others, 1889); *Studie Pamphylicus und Pisidiens* (with Niemann and Count Lanckoronski, 1890-92); *Vom alten Rom* (1898; 2d ed. 1900); and *Trajans dakische Kriege nach Säulenrelief* (1899 sqq.).

PETERSEN, JOHANN WILHELM (1649-1727). A Lutheran mystic. He was born at Osnabrück, taught at Rostock and Giessen, and preached acceptably at Hanover. In 1678 he became superintendent of Lübeck. Ten years later he was chosen to a similar position at Lüneburg, but his millenarian views led to his summary removal and banishment in 1692. He went to Magdeburg and spent the rest of his life preparing pamphlets and treatises explaining and defending his views. Petersen was the leading Lutheran mystic and premillenarian of the seventeenth century. He was entirely orthodox and conventional except

upon various points, such as the thousand years' reign of Christ upon earth and the apokatastasis or doctrine of universal restoration. Petersen wrote his autobiography, *Lebensbeschreibung* (2d ed., Frankfort, 1719). One of his treatises, *Die Stimme aus Zion*, appeared in Ebenezer, N. Y. (1851-52).

PETERSEN, NIELS MATTHIAS (1791-1862). A Danish scholar and historian of literature, born at Sandown, on the island of Fünen. He was appointed professor in the Normal School of Brahetrolleborg, was employed in the State archives, and in 1845 was chosen professor of Scandinavian languages in the University of Copenhagen. Petersen wrote on mythology, history, geography, and above all literary history. His most important works are *Bidrag til den old Nordiske Literaturs Historie* (1866), and *Bidrag til den Danske Literaturs Historie* (1853-64; 2d ed. 1867-71), a valuable work which stops with the beginning of the nineteenth century.

PETER SIMPLE. A novel by Captain Marryat (1834). This rollicking sea-tale gives the adventures of a clergyman's son, a midshipman on a man-of-war. He cruises in the Mediterranean and the West Indies. A scheming uncle tries to injure him, finally consigning him to an insane asylum. But he escapes and succeeds his grandfather as Lord Privilege.

PE'TERSON, FREDERICK (1859—). An American neurologist and alienist, born at Faribault, Minnesota. In 1879 he was graduated from the medical department of the University of Buffalo. After several years in Europe, he became, in 1882, professor of general pathology and director of the laboratory of the University of Buffalo. In 1888 he established himself in New York City as a specialist in nervous and mental troubles. In 1893-94 he was professor of neurology at the University of Vermont. For several years he was professor of neurology in the Women's Medical College, pathologist in the New York City Insane Asylum, and attending physician to the New York Hospital for Nervous Diseases and to the St. Saviour's Sanatorium for Inebriate Women. He also became chief of clinic in the Department of Nervous Diseases of the College of Physicians and Surgeons of Columbia University, New York City. He became president of the New York State Commission in Lunacy in 1900. Dr. Peterson is one of the editors of the *New York Medical Journal* and the *Journal of Mental and Nervous Diseases*. For many years he was an editor of the *American Medico-Surgical Bulletin*. Besides monographs, he has written a book on *Mental Diseases* (1899), which is a part of Church and Peterson's *Nervous and Mental Diseases* (1899).

PETER'S PENCE. The name given to offerings made for the support of the Pope. As a definite historical tribute, it seems to have had its origin in England, from which it spread to Denmark and Norway under Canute. The origin of the payment has been attributed to Ina, King of the West Saxons, and by others to Offa and to Ethelwulf; but the question is still obscure; Lingard is disposed not to trace it further back than the time of Alfred. It was collected annually in the month of July, or between the feasts of Saints Peter and Paul and of Saint Peter's chains. It consisted in the payment of a silver penny by every family that possessed land or cattle of the yearly value of thirty pence. The payment was finally abolished under Henry VIII. Latterly the name has been often applied to the voluntary offerings for the support of the Holy See made by its subjects in all parts of the world, since the loss of its territorial possessions has made other support necessary.

PETERSSEN, pā'tĕr-sen, EILIF (1852—). A Norwegian painter, born in Christiania. He was a pupil of Riefstahl and Descoudres at Karlsruhe and of Dietz in Munich. He first painted costume pictures, such as "Christian II. Signing a Death Warrant" (1876, Breslau Museum); then religious subjects, in which he was influenced by the Venetians, whom he studied in Italy; and finally genre and landscapes. "The Laundresses" (1889) and "Woodland Lake" (1891) are examples of his fine and harmonious color, in the genre in which he is most successful. The Museum at Christiania contains a "Siesta," and the New Pinakothek at Munich a "Summer Night in Norway."

PETERWARDEIN, pā'tĕr-vär-dīn' (Hung. *Péterrárad*). A free town and strong fortress of Croatia and Slavonia, Hungary, situated on a promontory on the right bank of the Danube opposite Neusatz, with which town it is connected by two bridges (Map: Austria, G 4). The fortifications consist of the old fortress on the lofty rock and the lower fortress at its base. Population, in 1900, 5019. Peterwardein is believed to occupy the site of the Roman *Acumincum*. The fortress was captured by the Turks in 1526 and was the scene of the defeat of the Grand Vizier Ali by Prince Eugene in 1716, after which it was awarded to the Emperor by the Peace of Passarowitz in 1718.

PET'IGRU, JAMES LOUIS (1789-1863). An American jurist, born in Abbeville District, S. C. He graduated at the College of South Carolina in 1809, and taught until his admission to the bar in 1812. He began practice in this district, volunteered for the defense of Port Royal against a threatened British attack in 1813, and soon afterwards was elected solicitor of the district. In 1819 he accepted an advantageous partnership in Charleston, and was elected Attorney-General of the State in 1822. When the issue of nullification (q.v.) was presented he was prominent in the Union Party, and resigned his office in 1830 to become a candidate for the State Senate. He was defeated, and incurred much unpopularity. From 1850 to 1853 he was United States District Attorney, and later was selected to codify the laws of South Carolina, which task was finished in 1862. He vigorously opposed secession, but preserved the respect of his fellow citizens. His bust was placed in the City Hall of Charleston in 1883. Consult Grayson, *James Louis Petigru* (New York, 1866).

PETIOLE (from Lat. *petiolus*, stalk or stem of fruits, irregular diminutive of *pes*, foot). The stalk-like portion of a leaf (q.v.).

PÉTION, pā'tyôN', ALEXANDRE SABES (1770-1818). A Haitian general and politician, born at Port-au-Prince, April 2, 1770, the son of a white father and a mulatto mother. He received a good education and fought for his country's independence under Toussaint L'Ouverture. Later he joined General Rigaud against L'Ouverture, went to France in 1800, and returned in 1802 with General Leclerc. He subsequently served under

Dessalines (q.v.) against the French. Upon the death of Dessalines and the succession of Christophe (q.v.) the southern part of the island set up an independent republic and Pétion, who was Governor of Port-au-Prince, was chosen President in 1807. There followed a civil war with Christophe, which desolated the country for many years. Pétion remained at the head of the Government in the southern part of the island until his death. While in power Pétion displayed an amount of moderation strange in a Haitian politician. He protected the foreigners in the country and made some attempts to preserve the national credit. A sketch of his military and political career is given in St. John's *Hayti; or, The Black Republic* (London, 1884).

PÉTION DE VILLENEUVE, *de vél'nëv'*, JÉRÔME (1756-94). A French revolutionist. He was the son of a procurator at Chartres, and was practicing as an advocate in his native city when he was elected in 1789 a Deputy to the States-General. He became a prominent member of the Jacobin Club, and an ally of Robespierre. He was sent as one of three commissioners to bring back the royal family from Varennes after their attempted flight, and in the execution of this commission he acted in a harsh and unfeeling manner. In November, 1791, he was elected Mayor of Paris to replace Bailly. He became a member of the Convention, and on September 20, 1792, its first president. He favored the Girondists, and although at the trial of the King he voted for his death, he was suspected of being a Royalist, and of complicity in the treason of Dumouriez. He was thrown into prison, June 2, 1793, on the fall of the Gironde, but escaped and joined the other Girondists at Caen. In company with Buzot he reached the neighborhood of Bordeaux. A short time after, their dead bodies were found in a field near Saint Emilion, and they were supposed to have committed suicide. The public career of Pétion shows him to have been weak, shallow, ostentatious, and vain. The *Œuvres de Pétion*, containing his speeches and some small political treatises, were published at Paris, in 4 vols. (1793). Consult also *Mémoires inédites*, edited by Dauban (Paris, 1866), and Vatel, *Charlotte Corday et les Girondins* (ib., 1872). See FRENCH REVOLUTION.

PETIT DE JULLEVILLE, *pe-tē' de zhul'vēl'*, LOUIS (1841—). A French historian, born in Paris. From the Ecole Normale (1860-63) he went to the French School in Athens, was made doctor of letters in 1868, and, after teaching rhetoric in the Collège Stanislaus, Paris, removed to Dijon. Thence he returned to Paris, where he became professor of French mediæval literature and of the history of the French language in the Faculty of Letters (1886). Three of his works were crowned by the Academy, and besides text-books on his subject, he published *Histoire de la Grèce sous la domination romaine* (1875); *Histoire du théâtre en France: Les mystères* (1880); *Les comédiens au moyen âge* (1885); *La comédie et les mœurs en France au moyen âge* (1886); *Le théâtre en France* (1889). In 1896 he began the publication of a *Histoire de la langue et de la littérature française*, in eight volumes.

PETITION (Lat. *petitio*, from *petere*, to seek; connected with Gk. *πίτνᾱσθαι, pitnasthai*, Skt. *pat*, to fly). A supplication preferred to one capable of granting it. The right of a British subject to petition the sovereign or either House of Parliament for redress of grievances is a fundamental principle of the English Constitution and has been exercised from very early times. The right was so generally exercised in the time of Edward I. and Edward II. that it became necessary to formulate rules and methods by which the task of hearing petitions could be facilitated. Those which could not be answered without special reference to the King formed a special branch of business, and it was from the share of the Chancellor in examining and reporting on petitions for clemency and favor that his equitable jurisdiction grew up in the fourteenth century. The nomination of 'receivers' and 'triers' of petitions became a part of the opening business of every Parliament, and proclamation was made inviting all persons to resort to the receivers. The receivers were clerks or masters in chancery; the triers were selected by the King from the Lords, spiritual and temporal, and from the justices. The triers could call to their assistance the Chancellor, Treasurer, Steward, and Chamberlain. After examining into the nature of the grievances for which redress was sought, they referred the petitions to certain of the courts or to Parliament for further action.

In the time of Richard II. the work of receiving and hearing petitions was divided into three parts; one part for the consideration of the King, one for the Council, and one for Parliament. The increasing power of the Commons over taxes and expenditures vastly augmented the importance of the right of petition to the Crown. In the fourteenth century they began the policy of accompanying their grants with petitions for redress in the name of the whole community. Later the petition for redress preceded the grant, and the latter was made conditional upon the promise of the King to provide the desired relief.

Since the revolution of 1688 the practice has been gradually introduced of petitioning Parliament, not so much for the redress of specific grievances as regarding general questions of public policy. Petitions must be in proper form and respectful in language; and there are cases where petitions to the House of Commons will only be received if recommended by the Crown. A petition must, in ordinary cases, be presented by a member of the House to which it is addressed; but petitions from the Corporation of London may be presented by the sheriffs or Lord Mayor. Petitions from the Corporation of Dublin have also been allowed to be presented by the Lord Mayor of that city.

The practice of the House of Lords is to allow a petition to be made the subject of a debate when it is presented; and unless a debate has arisen on it, no public record is kept of its substance, or the parties by whom it is signed. In the House of Commons petitions not relating to matters of urgency are referred to the Committee on Public Petitions, and in certain cases ordered to be printed.

The Constitution of the United States, like that of Great Britain, guarantees to every citizen the right of petition for a redress of grievances.

This constitutional right was practically nullified once in our history by the action of the National House of Representatives in the case of those petitions which related to the abolition of negro slavery. This was the so-called 'gag' resolution of January, 1840, which pro-

[illegible] anti-slavery petition should be re- [illegible] and by the House of Representatives.

PETITION AND ADVICE, THE HUMBLE. A written constitution of England during the Protectorate. The first Parliament elected according to the Instrument of Government (q.v.) was dissolved because it assumed the function of altering the Constitution under which it was called. A second Parliament was summoned by Cromwell, who was in urgent need of money, to meet on September 17, 1656, but nearly one hundred of its members had to be excluded as hostile to the Protector's Government. After this purge the assembly was ready to carry out Cromwell's wishes, asked him to take the title of King, and laid before him for approval a 'Humble Petition and Advice.' This may be regarded as practically an amended constitution, although it did not entirely supersede the Instrument of Government. The Protector declined the royal title, but after some alteration the Humble Petition and Advice was passed, and received his assent on May 25, 1657. On the 26th of the following month it was somewhat modified by the 'Additional Petition and Advice,' designed mainly to explain certain doubts and questions which had arisen. As a result of the two instruments the powers of the Council of State were lessened and those of the Parliament were increased. Henceforth the latter was to consist of two Houses, and the Protector was not again to exclude from sitting therein those who had been legally elected. As some compensation for this loss of authority, he was allowed to appoint his successor and to nominate the life members of 'the other House,' which was substituted for the House of Lords. The text of the Petition is contained in Gardiner, *Constitutional Documents* (Oxford, 1889), and Scobell, *Acts and Ordinances* (London, 1658). Consult also: Masson, *Life of Milton* (ib., 1873-94); Lingard, *History of England*, vol. viii. (ib., 1883). See CROMWELL, OLIVER.

PETITION OF RIGHTS. A declaration of certain rights and privileges of the subject obtained from King Charles I. in his third Parliament (1628). It was so called because the Commons stated their grievances in the form of a petition, refusing to grant the supplies till its prayer was heard. The petition is supposed to be a mere corroboration and explanation of the ancient Constitution of the kingdom; and after reciting various statutes, recognizing the rights contended for, prays "that no man be compelled to make or yield any gift, loan, benevolence, tax, or such like charge, without common consent by act of Parliament; that none be called upon to make answer for refusal so to do; that freemen be imprisoned or detained only by the law of the land, or by due process of law, and not by the King's special command, without any charge; that persons be not compelled to receive soldiers and mariners into their houses against the laws and customs of the realm; that commissions for proceeding by martial law be revoked." The King at first eluded the petition, expressing in general terms his wish that right should be done according to the laws, and that his subjects should have no reason to complain of wrongs or oppressions; but at this reply the Commons expressed dissatisfaction and prepared a remonstrance against the advisers of the King. The King thereupon ordered them not to meddle with affairs of State. The Commons then took up the charges against Buckingham, when the King yielded to their demands and gave his assent to the petition, June 7, 1628.

PETITIO PRINCIPII, pē-tĭsh'ĭ-ō prĭn-sĭp'ĭ-ī (Lat., begging of the question). The name given in logic to that species of vicious reasoning in which the proposition to be proved is assumed in the premises of the syllogism.

PETIT JOURNAL, pe-tē' zhōōr'nâl', LE. A daily paper, founded at Paris in 1863, republican in politics. Its low price commands for it an immense circulation throughout the country as well as in Paris.

PETITOT, pe-tē'tō', JEAN (1607-91). A French painter in enamel, born in Geneva. He learned the jeweler's trade and early began to use enamel in connection with his work. About 1634 he went to England and there met Van Dyke, who introduced him to the notice of Charles I. He had apartments in Whitehall and made various portraits of the King and his Court. One of the Duchess of Southampton (1642), in the collection of the Duke of Devonshire, is called his masterpiece. After the King's death he went with the royal family to Paris, where he enjoyed the favor and patronage of Louis XIV. He lived in the Louvre and painted the King, Anne of Austria, Madame de Maintenon, La Vallière, and others of the time. These are included in the collection of his works in the Gallery of Apollo, in the Louvre. They are done with great delicacy and particularly harmonious color. The Revocation of the Edict of Nantes in 1685 sent him back to Geneva, despite the fact that Louis had Bossuet himself try to convert him. He died in Vevey. His works are scarce and of high value.

PETIT-QUEVILLY, pe-tē' ke-vē'yē'. A town of France in the Department of Seine-Inférieure, situated two miles southwest of Rouen. Its principal industries are cotton and linen spinning and the manufacture of shoes, chemicals, starch, and soap. Population, in 1901, 13,948.

PETIT-THOUARS, tōō'ār'. ABEL AUBERT DU. See DUPETIT THOUARS, ABEL AUBERT.

PE'TO, Sir SAMUEL MORTON (1809-89). An English contractor and politician, born in Woking, Surrey. He was apprenticed to his uncle, a builder, at whose death in 1830 he and his cousin, Thomas Grissell, inherited the business and established the firm of Grissell and Peto. They secured a number of important contracts, among them those for the Conservative and other club-houses, several London theatres, the Nelson Column, the Houses of Parliament, and a large part of the Great Western and the Southeastern railroads. In 1846 they dissolved their partnership, Grissell taking the building and Peto the railroad contracts. The same year Peto took Edward L. Betts into partnership with him, and the new firm secured contracts for railroads in England, France, Norway, Denmark, Russia, Canada, and Australia. During the Crimean War Peto constructed a railroad between Balaclava and the intrenchments, which proved of great service and for which he was created a baronet in 1855. He served several terms in Parliament, but in 1868 was obliged to resign because of the failure of his firm during the financial panic of 1866. Consult *Sir Morton Peto, a Memorial Sketch* (1893).

PETÖFI, pĕ'tē-fī, SÁNDOR (ALEXANDER) (1822-49). The national poet of Hungary, born

at Kis-Körös, in the County of Pesth, December 31, 1822. His father was a butcher and a small landowner in Little Cumania, and bore the name of Petrovics—a name indicating a Slavic origin. In 1838 his father was impoverished by an overflow of the Danube, which destroyed his little estate; and it was only by the help of kinsmen that he was able to rear his son for a profession. Petöfi was sent to the lyceum of the town of Schemnitz. He ran away with a band of German strollers, and again from school at Oedenburg, this time enlisting as a common soldier. After two years in the army, a physician brought about his discharge, and he went home. He afterwards went to Pápa, to complete his education. In 1842 he left Pápa to join a troop of comedians, but he soon parted from them. He made his way to Pressburg, and afterwards to Pesth, where he got some employment as a translator from the English and the French. Going to Debreczin, he made another venture as an actor, playing the part of Othello, but again failed. At last he had the good fortune to be invited to contribute to a newspaper at Pesth. On his arrival at that city he exchanged the name of Petrovics for Petöfi, and it was not long before he became famous as a lyric poet.

Petöfi introduced himself to Vörösmarty, then the poet of Hungary, who received the shabby stranger coldly, but when he had listened to his verses he exclaimed, "Hungary never had such lyrics; you must be cared for." And from that time he treated Petöfi as a son. Petöfi was almost at once received into the literary national circle, at the expense of which was published his *Versek*, which appeared in 1844. This was rapidly followed by other volumes, which won boundless popularity. In March, 1848, he was the leader in the first movement of the Hungarian revolution at Pesth, and he became, by speech and pen, the advocate of the independence of Hungary. His poem, *Talpra, Magyar!* (Up, Magyars!), like later stirring lyrics, excited great patriotic enthusiasm. He enlisted in the National Army, and in the beginning of 1849 he was appointed adjutant and secretary to General Bem. Petöfi was at the battle of Schässburg (Segesvár), fought on July 31, 1849, in which Bem's army was overwhelmed. He was never heard of after that day. It is believed that he was killed by a Cossack in the flight, and that his body, so mangled as to escape recognition, was buried with the multitude of Magyar dead left upon the field. His countrymen at first believed that he was not dead, but a prisoner in an Austrian dungeon. In 1877 a rumor gained currency that Petöfi was still living as a Russian prisoner in one of the mines of Siberia, and the Austrian Government was forced by public opinion to institute official inquiries in order to prove the groundlessness of the report. On October 15, 1882, a monument to the poet was unveiled in Petöfi Square at Budapest, and the house in which he was born at Kis-Körös was purchased with the intent to preserve it. He left a widow and one son.

Petöfi is the greatest literary genius of Hungary, and he ranks, by common critical consent, among the greatest lyric poets of the last century. The most beautiful of his poems are his impassioned shorter lyrics, of which he published several collections, under the titles *Cypress Leaves on Etelka's Grave; Pearls of Love; Starless Nights; Clouds.* The most celebrated of his narrative poems—also the longest—are: *Janos, the Hero; Istok, the Fool.* His earliest work was *The Wine-Drinkers*, published in 1842; his latest, *The Assessor of the Judgment-Seat*, which appeared in 1849. Petöfi translated Shakespeare's *Coriolanus* in 1848. A volume, containing a poem entitled *The Apostle*, was suppressed by the Austrian Government after the pacification of Hungary. Petöfi published a novel, *The Hangman's Rope*, which failed, like his play *Tigr and Hyena*, and he wrote several volumes of tales, criticisms, and sketches of travel; he also translated largely from English and French into Magyar.

A selection from his earlier pieces, translated into German, was published in 1845; and several volumes of translations from his writings have since appeared in Germany. His poems have also been translated, in part, into French, Flemish, Polish, Danish, and Italian; and an English version, comprising his finest poems, was published in London in 1866 by Sir John Bowring. A critical edition of his works is in preparation by A. Haras, who has already published a number of volumes. Consult: Fischer, *Petofis Leben und Werke* (Leipzig, 1889); Bubenik, *A. Petofi, eine Skizze seines Lebens und Dichtens* (Vienna, 1882); and the biographies in Magyar by Zilahy (Pest, 1864) and A. Vutkovics (Pressburg, 1883).

PETOS'KEY. A city in Emmet County, Mich., 43 miles southwest of Cheboygan; on Little Traverse Bay, an arm of Lake Michigan, and on the Grand Rapids and Indiana and the Pere Marquette railroads (Map: Michigan, H 3). Steamers ply to several of the important lake ports. Petoskey is an attractive summer resort, and has a public library and the Petoskey Normal School. There are iron works, a foundry and machine shops, lime kilns, lumber and flour mills, a leather factory, rug and carpet factory, etc. The water-works and electric light plant are owned by the municipality. Petoskey was incorporated as a village in 1878 and in 1896 became a city. Population, in 1890, 2872; in 1900, 5285.

PE'TRA (Lat., from Gk. *πέτρα*, rock). An ancient city of Northern Arabia, in the 'desert of Edom,' about 70 miles northeast of Akabah (Map: Turkey in Asia, F 7). It occupied a narrow rocky valley, overhung by mountains, the highest and best known being Mount Hor, directly to the west. Petra owes its name to its peculiar character as a 'rock-city,' which also gave it the Hebrew name, *Sela'*, 'rock' (II. Kings xiv. 7; Is. xvi. 1). Its importance was due to its location on the great highway from the Red Sea and Arabia northward, while its situation protected it from Bedouin raids. It thus became an important centre of trade. In the ninth century B.C. it was captured by King Amaziah of Judah, who changed the name to Joktheel, according to II. Kings xiv. 7. In the second or third century B.C. it fell into the hands of the Nabateans (q.v.). From the time of Pompey it was tributary to the Romans. In 105 Trajan made a province of Arabia Petræa (the name being taken from the city) and Hadrian granted certain privileges to the town. Christianity was introduced at an early period and Petra became the seat of a bishop. In the fourth or fifth century trade began to follow other channels and the importance

[illegible] the Mohammedan conquest [illegible] unknown to Europeans [illegible] the nineteenth century, when it was [illegible] Seetzen and Burckhardt. Since then the remarkable remains of Petra have become well known. They stand in a small open irregular basin, about half a mile square, through which runs a brook, and are best approached by an extraordinary chasm or ravine called the *Sik* (or Wady Musa), narrowing as it proceeds till in some places the width is only 12 feet, while the rocky walls of red sandstone tower to the height of 80 to 200 feet. Hardly a ray of sunlight can pierce this gloomy gorge, yet it was once the highway to Petra, and the remains of an ancient pavement can be traced beneath the brilliant oleanders that now cover the pathway. All along the face of the rocky walls are rows of cave tombs, hewn out of the solid stone, and ornamented with façades. These are also numerous elsewhere in and about the city. The principal ruins are: (1) *El-Khazneh* ('the treasure house'), believed by the natives to contain, buried somewhere in its sacred inclosure, the treasures of Pharaoh; it directly faces the mouth of the gorge of Wady Musa and was probably the great temple of the Petreans; (2) the amphitheatre, capable of containing from 3000 to 4000 spectators; (3) certain remarkable tombs; (4) the *Dair* or convent, a huge monolithic temple, hewn out of the side of a cliff and facing Mount Hor; (5) the citadel; (6) *Kasr Fir'aun*, or Pharaoh's palace, the best preserved ruin of Petra, east of which are the remains of a triumphal arch. Most of the architecture is Greek of the third or fourth century, but forms of native art are intermixed, and there are also traces of Egyptian influence, pyramidal forms being not unknown. Consult: Laborde and Linant, *Voyage dans l'Arabie Pétrée* (Paris, 1830); De Luynes, *Voyage aux bords de la Mer Morte, Petra*, etc. (ib., 1875); Palmer, *The Desert of the Exodus* (Cambridge, 1871); Visconti, *Diario di un viaggio in Arabia Petrea* (Rome, 1872).

PETRARCH (It. **PETRARCA**, pā-trär'kä), Francesco (1304-74). An Italian poet and humanist, born at Arezzo, July 20, 1304, of a family then in exile from Florence, because of its affiliation with the party of the Bianchi. Francesco changed his father's name Petracco to Petrarca. The wanderings of the family took the lad to Pisa in 1310 and in 1313 to Avignon in France. After some preliminary training he was sent to Montpellier in 1319 to study law. After some four years there he went to Bologna unwillingly to continue his studies in jurisprudence, for he shrank from pettifogging, though he admired the majesty of Roman law. He had an unbounded love for classical lore, and to this he devoted himself after the death of his father (1326), who had once flung his son's books of poetry and rhetoric into the flames, allowing the half-burnt manuscripts to be rescued at Francesco's passionate entreaty. In 1326 he returned to Avignon and took minor orders as an ecclesiastic. Thus he was not bound by the stricter laws of ecclesiastical discipline, and yet he could enjoy the numerous religious benefices accorded to him. It may be said here that Petrarch was no skeptic like Boccaccio and that his piety was of a worthy kind. He entered into the gay and fashionable life of Avignon, and there he met in 1327 that Laura who was to inspire his imperishable lyrics. The historical reality of this personage has often been doubted. On the other hand, many endeavors have been made to identify her with this or that woman. The only probable identification seems to be that with Laura de Noves, wife of Hughes de Sade and mother of eleven children at the time of her death by the plague of 1348. However unpoetical the circumstances of her life may have been, she aroused in the poet that spirit of devotion which stirred him in the composition of sweeter lyric verse than had yet been heard in Italy.

Yielding to his nomadic impulses, Petrarch roved about for a while, traveling through Southern France and Germany in 1333, and entering Rome for the first time in 1337. In 1337, eleven years before Laura's death, some unknown woman bore Petrarch a son, Giovanni, and probably it was she who gave him a daughter Francesca in 1343. These children were legitimized by Papal bulls. At intervals he was back again in Avignon, and thence he withdrew for a while to the solitude of Vaucluse (Valchiusa). It was here that he received in 1340 from the universities of Paris and of Rome invitations to visit those places and receive the crown of the poet laureate. He decided in favor of the University of Rome, and on Easter Sunday, 1341, he was publicly crowned on the Capitol. He now visited many Italian cities and in 1343 was sent by Pope Clement VI. on an embassy from Avignon to Naples. Resuming his rambles about Italy, he had the good fortune to discover some of the letters of Cicero, just as he had earlier brought to light two of Cicero's orations. He may also have found a part of the *Institutiones* of Quintilian. At Parma he got tidings in 1348 of Laura; in 1350 he was in Florence with Boccaccio, and in 1351 Boccaccio visited him at Padua. Having refused several offers of apostolic secretaryships from the Holy See, he left Avignon for good in 1353. About this time began his connection with the Visconti in Milan, who in 1356 sent him to Prague as ambassador to Charles IV. of Germany, and in 1360 he undertook a similar mission to Paris. The remaining years of his life were mainly spent in scholarly pursuits at Arqua, near Padua, and there he died July 18, 1374.

Petrarch wrote much more in Latin than in Italian, and prided himself more on his Latin writings than on those in Italian. His works in Latin consist chiefly of a poem in hexameters, the *Africa*, dealing with the undertakings of Scipio Africanus, and of moral, historical, and other scientific treatises, as well as of letters. All his Latin compositions are now forgotten, yet mention may be made of the *Carmen Bucolicum* and the *Epistolæ Metricæ*, which contain many allusions to events of his time and life, as do also his *Letters*, for which reference may be made to Voigt, "Die Briefsammlungen Petrarkas," in the *Abhandlungen der historischen Classe der bayerischen Akademie der Wissenschaften*, vol. xiii. (Munich, 1883). Petrarch's Latin shows the influence of Seneca and of his beloved Saint Augustine, rather than of the best classics. Indeed, Petrarch still belongs to the mediæval school, and it remained for a Poliziano and a Bembo to prepare the way for an Erasmus. The *Canzoniere*, containing his Italian verse, is the work for which Petrarch is now remembered. It comprises sonnets, *canzoni*, *sestine*, *ballate*, and madrigals, mainly of an amorous nature, and de-

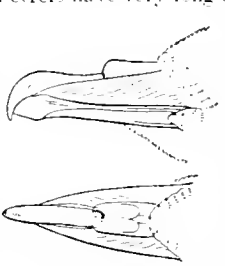
PETRARCH

FROM AN ENGRAVING [illegible]

voted to an account of his love for Laura, although some deal with political and other subjects. On the formal side Petrarch shows a considerable advance over his forerunners, whose methods he developed. As to the love that he sang, it can hardly be doubted that its object was a single and concrete one, even though the description of the passion often takes a highly symbolized and idealized form. Certainly Laura is not a woman, but woman in general. She has no strongly individualized traits. She is rather the noblest abstraction of fair womanhood to be found in literature between Dante's Beatrice and the period when poets began to sing of women undeniably flesh and blood. In the minute psychological examination of his own sentiments Petrarch shows some knowledge of the human heart, but, after all, his sonnets lack striking individuality. What one notices most is the poet's astounding ability to vary a few lovely or noble themes. In his pictures of natural scenery he displays an observation of the external phenomena of the world not to be found in other writers of his time. Yet Petrarch's descriptions of the beauties of Valchiusa might fit many another place as well. Valchiusa is not more individualized than Madonna Laura. The *Trionfi*, published with the other Italian verse of the *Canzoniere*, are an imitation of the allegorical vision of Dante. The vogue of the lyrics of Petrarch became enormous almost at once after the appearance of the first edition of the *Canzoniere* (Venice, 1470). It continued for many generations and spread abroad. Thus a very marked influence of his poetical methods is to be noted in Spanish verse of the sixteenth and seventeenth centuries. As a humanist, Petrarch went far to revive the study of Greek literature, although he was himself ignorant of the language; he was most successful, however, in the impulse which he gave to the study of Latin letters. As a writer of Italian, he shows in his style a degree of precision and refinement which indicates an improvement upon the art of Dante. But his style is marked by artificiality and many conceits such as we find in the troubadours.

Consult the edition of Petrarch's Latin and Italian works, published at Basel in 1554; also a critical edition of the *Africa* by Corradini (Padua, 1874, with an Italian translation by Gaudo, Oneglia, 1874); the *Poemata Minora* (Milan, 1829-34); the editions of the *Canzoniere* by Mestica (Florence, 1895), and by Carducci and Ferrari (Florence, 1899); the editions by Fracassetti (Florence, 1859-63) of the *Epistolæ de Rebus Familiaribus et Variæ*, published in Italian as the *Lettere di Francesco Petrarca (familiari e varie) volgarizzate e dichiarate* (Florence, 1863-67), and *Lettere scelti, etc.* (ib., 1869-70); Marsand, *Biblioteca petrarchesca* (Milan, 1826); Hortis, *Catalogo delle opere di Francesco Petrarca*, etc. (Triest, 1874); Ferrazzi, *Bibliografia petrarchesca* (Bassano, 1887); Fiske, *Catalogue of Petrarch Books* (Ithaca, N. Y., 1882); id., *Hand-List of Petrarch Editions in the Florentine Public Libraries* (Florence, 1886); Mézières, *Pétrarque*, etc. (Paris, 1867); Geiger, *Petrarca* (Leipzig, 1874); P. de Nolhac, *Pétrarque et l'humanisme* (Paris, 1892); Körting, *Petrarcas Leben und Werke* (Leipzig, 1878); D'Ovidio, "Madonna Laura," in the *Nuova Antologia* (July-August, 1888); Segre, *Petrarca e Chaucer* (ib., 1899).

PETREL (Fr. *pétrel*, from ML. **Petrellus*, diminutive of Lat. *Petrus*, Peter; so called in allusion to its walking on the sea, like the Apostle Peter). A sea-bird of the family Procellariidæ, containing several genera, and distinguished by having the bill hooked at the tip, and hard, and the nostrils united into a tube along the culmen, and the hind toe merely rudimentary. Petrels have very long and pointed wings, and the tail square or slightly forked. They possess great power of wing, and are among the most strictly oceanic of birds. Among the 70 species of the Procellariidæ are reckoned the fulmars and shearwaters (qq.v.), besides the many petrels proper, of which the stormy petrel is an example. They run along the surface of the waves in a remarkable manner, and with great rapidity—particularly when the sea is stormy and the mollusks and other animals that form their food come in abundance to the surface. From the frequency with which flocks of these birds are seen in windy weather, or as heralds of a storm, they are superstitiously regarded by sailors. They are to be seen in the seas of all parts of the world, but are more abundant in the Southern than the Northern Hemisphere.



TYPE OF PETREL BILL.

Side and top views of bill of pintado petrel (*Daption Capensis*); showing the tubular nostrils.

The names 'stormy petrel' and 'Mother Carey's chicken' are sometimes more particularly given to *Procellaria pelagica*, a bird scarcely larger than a lark, 5½ inches long, and the smallest web-footed bird known. It is sooty black in color, with a little white on the wings and near the tail. Two other species of petrel are of frequent occurrence in the North Atlantic, Leach's petrel (*Oceanodroma leucorrhoa*) and the better known Wilson's petrel (*Oceanites oceanicus*). The former may be recognized by its larger size (eight inches long) and its forked tail. It breeds among the islands in the Bay of Fundy, and in similar places in the North Pacific. The Wilson's petrel, on the other hand, is a bird of the Antarctic regions, and migrates during its winter (our summer) into the Northern Hemisphere. It is easily distinguished by its small size (seven inches long), the yellow on the webs of the feet, and the white upper tail-coverts. Besides these three species, no less than a dozen others have been recorded from the coasts or inland waters of the United States. Of these, one is a common Pacific Coast species, two others are known only from the coast of southern California, while the remaining nine are stragglers from the Southern Hemisphere. The 'cape pigeon' (*Daption Capensis*), or 'pintado,' is a very large species, well known to voyagers about the Cape of Good Hope; and in the Indian Ocean and about the shores of Australia occurs the giant of the family, the huge 'bone-breaker' (*Ossifraga gigantea*), which sailors call 'stinkpot,' and by other names referring to its vile odor. Petrels generally breed in holes and clefts of rock, or secluded coasts, and are likely to visit their nests (except when the female is sitting) only at night. Only a single egg is laid, as a rule, which is

[illegible] or with a few fine reddish dots. See Colored Plate of Eggs of American Water and Game Birds.

Consult: Evans, *Birds* (London, 1901); Baird, *Water Birds of North America* (Boston, 1884).

PETRI, pā'trē, Olaus (1493-1552). A Swedish reformer, born at Orebro, in the Province of Nerike. He studied at Upsala and the University of Leipzig, and afterwards at Wittenberg, where he continued his theological studies under Luther and Melanchthon. Upon the recommendation of King Gustavus I. he was appointed town clerk of Stockholm and at the same time preached in the cathedral, where he fearlessly expounded and urgently pleaded for the introduction of the reformed religious service. He wrote the first hymn-book in Swedish, also a Swedish chronicle (to 1520). This was published in the *Scriptores Rerum Suecicarum Medii* (1818). From 1531 to 1533 he was chancellor of the King, but his enthusiasm got him into trouble with his sovereign, and at one time seemed likely to cost him his life.—His brother, Laurentius (c. 1499-1573), was first Lutheran Archbishop of Sweden, and was born at Orebro. About 1527 he was appointed professor of theology at Upsala, and in 1531 he was elected first Lutheran Archbishop. He devoted his life to establishing the Reformed Church in this country. He drew up the first Swedish Evangelical Church order that was printed (1571), and with his brother translated the Bible into Swedish. He also wrote many theological treatises defending the principles of Church reform.

PETRIE, pē'trī, William Matthew Flinders (1853—). An English Egyptologist, born at Charlton, June 3, 1853, the son of William Petrie and Anne, daughter of Captain Matthew Flinders, the Australian explorer. He was educated at private schools, and at first turned his attention to the study of British archæology. His earliest works were *Inductive Metrology* (London, 1877), and *Stonehenge: Plans, Descriptions and Theories* (London, 1880). After 1880 he occupied himself with the investigation of Egyptian antiquities, and made many valuable discoveries. Between 1884 and 1886 he excavated the site of Tanis, Naukratis, and Daphne and revealed the existence of ancient Greek settlements at the two latter places. From 1888 to 1890 he worked in the Fayûm, finding a number of interesting funeral portraits at Hawara, and gathering an extensive collection of valuable papyri, chiefly from the ruins of Kahun and Gurob. In 1890 he discovered and excavated for the Palestine Exploration Fund the site of ancient Lachish at Tell el-Hesy, in Palestine. In 1893 he received the degree of D.C.L. from the University of Oxford and was appointed to the newly founded professorship of Egyptology at King's College, London. In 1895 he discovered the remains of a prehistoric race at Nagada, and the following year found at Thebes the stele of Meneptah, containing the sole mention of Israel occurring in the Egyptian inscriptions. After 1899 he investigated the very interesting tombs of the First Dynasty at Abdos. Among his more important works may be mentioned: *The Pyramids and Temples of Gizeh* (1883); *Tanis*, Memoirs II. and V. of the Egyptian Exploration Fund (1885-87); *Hawara* (1889); *Kahun* (1890); *Ten Years' Diggings* (1893); *A History of Egypt* (2d ed. 1897); *Egyptian Tales* (1895-99); *Religion and Conscience in Ancient Egypt* (1898); *Royal Tombs of the First Dynasty* (1900-01).

PETRIFACTION (from Lat. *petra*, from Gk. *πέτρα*, rock + *facere*, to make). A name given to organic remains found in the strata of the earth, because they are generally more or less mineralized or made into stone. The word has fallen into disuse, having given place to the term fossil (q.v.).

PETRIFIED FORESTS. The same as fossil forests (q. v.).

PETROBRUSIANS. See Bruys, Pierre de.

PETRIFIED WOOD. Plant remains in which the woody tissue has been replaced by mineral matter, usually some form of silica. The name dendrolites has been given to petrified fragments of plants that are commonly found in the coal measures. See Fossil Forests.

PETROGRAPHIC PROVINCE (from Gk. *πέτρα*, *petra*, rock + *γράφειν*, *graphein*, to write). A region within which the igneous rocks reveal a relationship (so-called consanguinity) in chemical composition, which may be referred to a community of origin. This relationship may be chemically a close one, but the rocks have widely varying mineralogical composition, or the kinship may be restricted to one or more of the chemical components in the rocks.

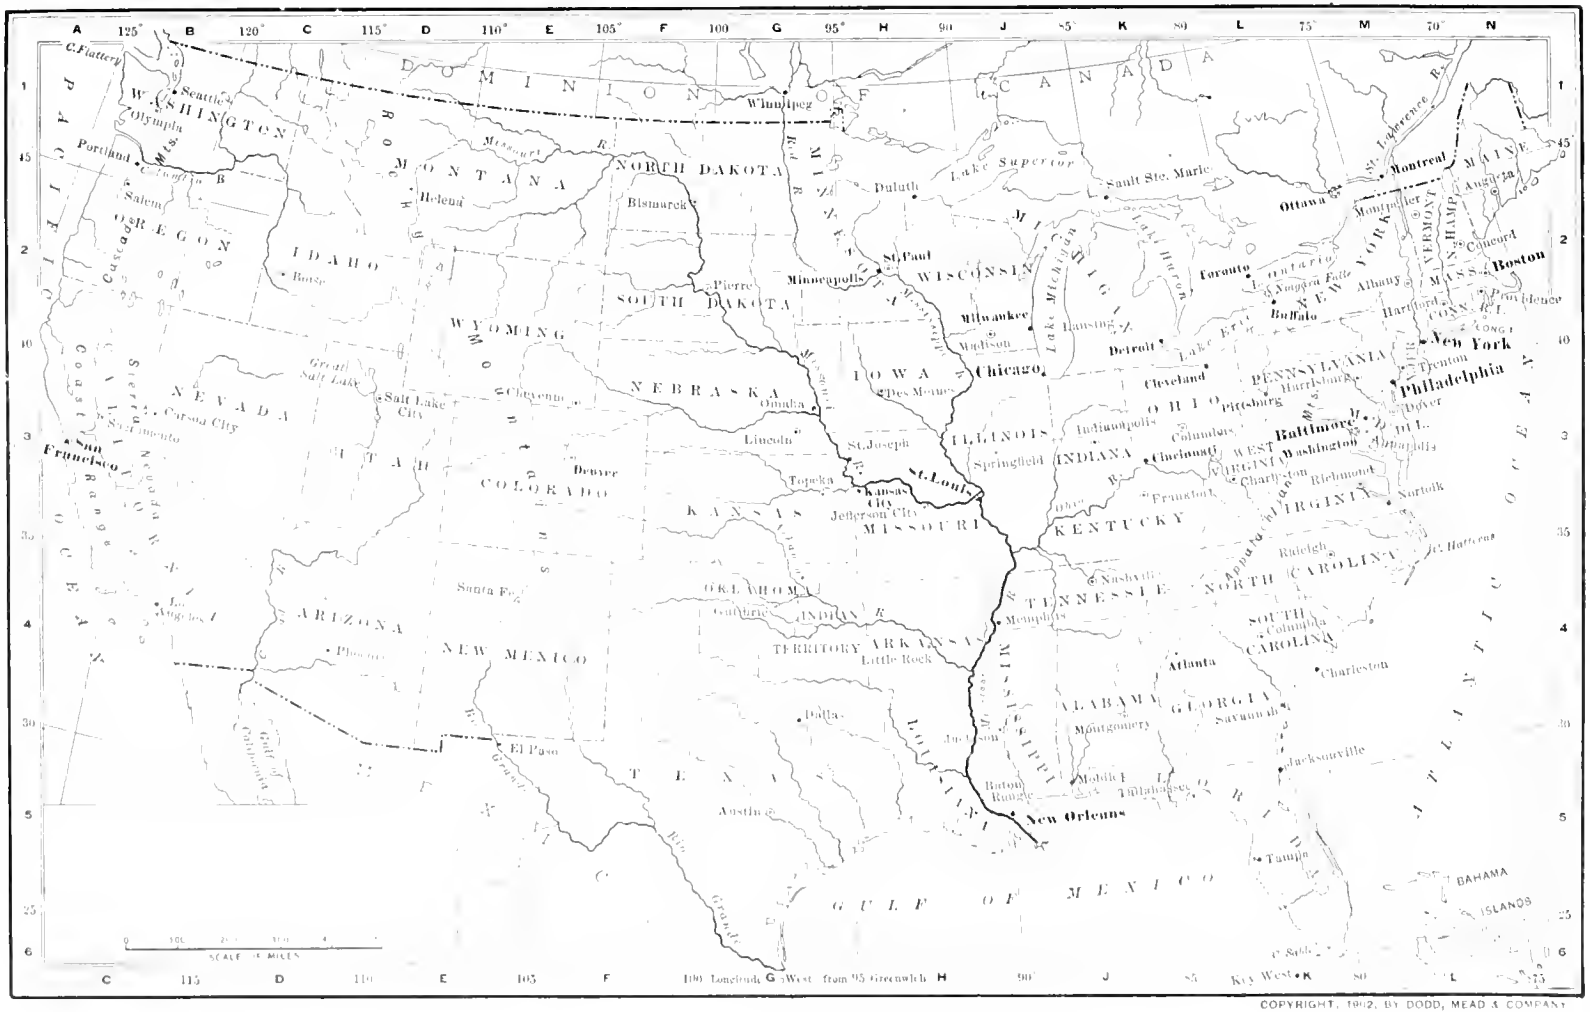
PETROG'RAPHY. See Petrology.

PETROLATUM (Neo-Lat., from ML. *petroleum*, rock oil, from Lat. *petra*, from Gk. *πέτρα*, rock + *oleum*, from Gk. *ἔλαιον*, *elaion*, oil). A residue from the distillation of petroleum, prepared by filtration, and known to the trade by different names, as petroleum jelly, vaseline, and cosmoline. It is an amber-colored, translucent, semi-solid substance, slightly soluble in alcohol, and readily so in ether. It does not become rancid, and is largely used in pharmaceutical preparations, especially ointments, instead of the ordinary fats. It is taken inwardly as a remedy for coughs and colds; it is an excellent lubricant, and will protect polished steel from rust. The term vaseline, while often applied to petrolatum in general, is really a trade name, protected by copyright, belonging to one particular preparation. See Petroleum.

PETRO'LEA. A town of Lambton County, southwestern Ontario, Canada, situated on a branch of the Grand Trunk Railroad, 16 miles east of the Saint Clair River. In the neighborhood are numerous oil wells producing yearly about 20,000 barrels of crude petroleum. Population, in 1891, 4357; in 1901, 4135.

PETROLEUM (ML., rock oil). A natural rock oil composed of hydrocarbons. It is classed with natural gas and asphalt as a bitumen; natural gas containing the more volatile members of the series, asphalt the solid, while petroleum is composed chiefly of the liquid members, although it contains a small proportion of both solid and gaseous compounds. Other names for petroleum are mineral oil, rock oil, and naphtha, the last being employed especially in Europe for the Russian oils.

History. Petroleum has long been known in various parts of the world by its appearance in the form of bituminous springs or as a floating scum on the surface of pools. It was used at a very early period in the walls of Babylon and Nine-



veh, and Herodotus has described the occurrence of oil springs in the island of Zachynthus, now Zante. In Roman times petroleum was obtained from Sicily and burned in lamps. The first mention of petroleum in America (about 1635) is in a letter written by the Franciscan missionary Joseph de la Roche d'Allion, who refers therein to springs found in the region of what is now southwestern New York or northwestern Pennsylvania. The early settlers of Pennsylvania obtained small quantities of oil by digging wells and scooping out the liquid which seeped in from the surrounding rocks. The drilling of brine wells on the western slopes of the Alleghanies in the early part of the nineteenth century led to the discovery of petroleum at greater depths. A well sunk near Burkesville, Ky., in 1829, yielded great quantities of oil, which flowed to the surface and was drained into the Cumberland River, where at one time it was set on fire. The most important application of petroleum in the early days was in medicine; it was utilized as an illuminant only to a small extent, owing to its offensive odor. In the year 1853 Dr. Brewer suggested the use of petroleum for lubricating and illumination purposes, and set to work devising means for purifying the crude product. The Pennsylvania Rock-Oil Company was organized in 1854 to drill for oil; although its first well yielded from 400 to 1000 gallons a day, the company was not successful in its business ventures. Five years later, however, Col. E. L. Drake put down a productive well on land leased from this company, and the successful outcome of this undertaking may be said to mark the beginning of the oil industry in the United States. The news of the discovery was followed by a rush of adventurers from all parts of the country, so that by 1860 more than 100 square miles of territory in the vicinity of Oil Creek had been shown to be productive. Much of the oil which reached the surface was allowed to escape, owing to the lack of storage and transportation facilities. As the explorations were extended new fields were opened along the Allegheny River in Pennsylvania, also in Ohio and West Virginia. The Lima field of Ohio and Indiana was first developed in 1885, while the California fields have become large producers only in the last few years. The discovery made in the Beaumont region of Texas early in 1901, which has been followed by extraordinary development, is the most important event in the recent history of petroleum.

Among foreign countries, Russia is the largest producer of oil and the strongest competitor of the United States in supplying the world's markets. Operations have been conducted in this country since 1873. The largest fields are located on the Apsheron Peninsula, Baku being the chief centre of the industry. The distillation of petroleum from shales was first undertaken in France in 1834, and was successfully introduced into Scotland in 1850. The importation of shale oil into America led to the use of cannel coal for distilling; this industry gained considerable importance in the United States previous to 1860, but quickly succumbed when the first wells became productive.

Origin and Geological Occurrence. The geological history of petroleum and natural gas are closely connected, so that what is said of one practically holds true of the other. Petroleum is always found in sedimentary rocks. For many years it was known only in sandstones or shales, and the term oil-sand was applied to the containing strata. Subsequently oil was struck in limestone in Ohio, thus forming a new type of occurrence, although one which has since proved to be rather unique.

Petroleum is considered by most geologists to have been derived by the destructive distillation of either animal or vegetable matter contained in the rocks. The products of this distillation have in some cases accumulated in the strata in which they were formed, while in others they have escaped upward into the overlying beds, in some instances even reaching the surface.

Petroleum occurs in all geological formations, from the Lower Silurian or Ordovician up to the Tertiary; it is chiefly of importance in the Silurian, Devonian, and Tertiary rocks. The relation of the distribution of oil to geological structure was not recognized until as late a date as about 1880, at which period geologists began to find the cause of oil accumulation and pressure. Prof. Edward Orton, of Ohio, was the most prominent investigator in this field. In all regions where petroleum occurs the strata are not only disturbed, but they are bent into anticlinal or arch-shaped folds. If the rocks are porous the gas tends to collect at the summit of the anticlinal fold or arch, while the oil collects in the flanks of the fold. Salt water is usually associated with the gas and oil, and, being heavier, accumulates in the flanks of the anticlinal or in the neighboring synclinal folds. There is little use of searching for oil in regions where the strata are flat; and it is rarely found in highly folded regions, for where the flanks of the fold have a dip of more than 10° the bending of the rocks is often sufficient to create cracks through which the oil or associated gas will escape to the surface. The rock in which the oil is found is spoken of as the reservoir, or oil-sand, and it is essential that this rock should be porous. The degree of porosity not only influences the quantity of oil which the rock can hold, but it may also influence the rate of flow of the well. Some wells may yield as little as 15 barrels per day; others may reach a production of 50,000 or 60,000 barrels per day. The porosity of the oil-bearing formation may also change from place to place and would account for the location of a profitable well at one point and a barren one a short distance from it. In order to prevent the escape of oil from the containing stratum it should also be overlain by a rock of more or less impervious nature. In many wells the petroleum flows to the surface under pressure. Professor Orton believed that the oil was under hydrostatic pressure; according to his theory, the pressure in different wells of the same basin or pool ought to be nearly constant. In any region, however, the pressure usually diminishes with time. While Orton's theory may be true for Ohio, it seems doubtful whether hydrostatic pressure will account for the great oil and gas pressure found in some regions. The quantity of oil which a given territory can yield is often very great, since some sand will hold as much as one-eighth of its bulk in oil under pressure. This means that there is 1.5 inches of oil to every vertical foot of oil-sand, or about 5000 cubic feet per acre.

Character and Composition. Petroleum is a liquid of varying color, being black, brown, red, amber, or straw, and by reflected light often ap-

[illegible] in tint. The black oils in the [illegible] obtained from the Trenton [illegible] of Ohio and from California; the Pennsylvania oils are of amber tint. In addition to the hydrocarbons, which are the chief constituents of petroleum, the following substances may be present: sulphur, nitrogen, hydrogen sulphide, carbon disulphide, arsenic, and phosphorus. The carbon percentage may vary from 79.5 to 88.7 per cent.; the hydrogen from 9.6 to 14.8 per cent.; the sulphur from 0.7 to 2 per cent., and in rare cases even 3 per cent.; nitrogen from 0.008 to 1.1 per cent. The hydrocarbons of all crude petroleums fall either into the paraffin or olefin group, those of America belonging chiefly to the first and those of Russia to the second group. The number of different members of the paraffin series present may be very large; some Pennsylvania oils, for example, have yielded 18 different paraffin compounds, as well as a number of substances belonging to the ethylene group. The hydrocarbons of the olefin series predominate in the Russian oils and many others. The composition of crude petroleum from a number of different localities is given below:

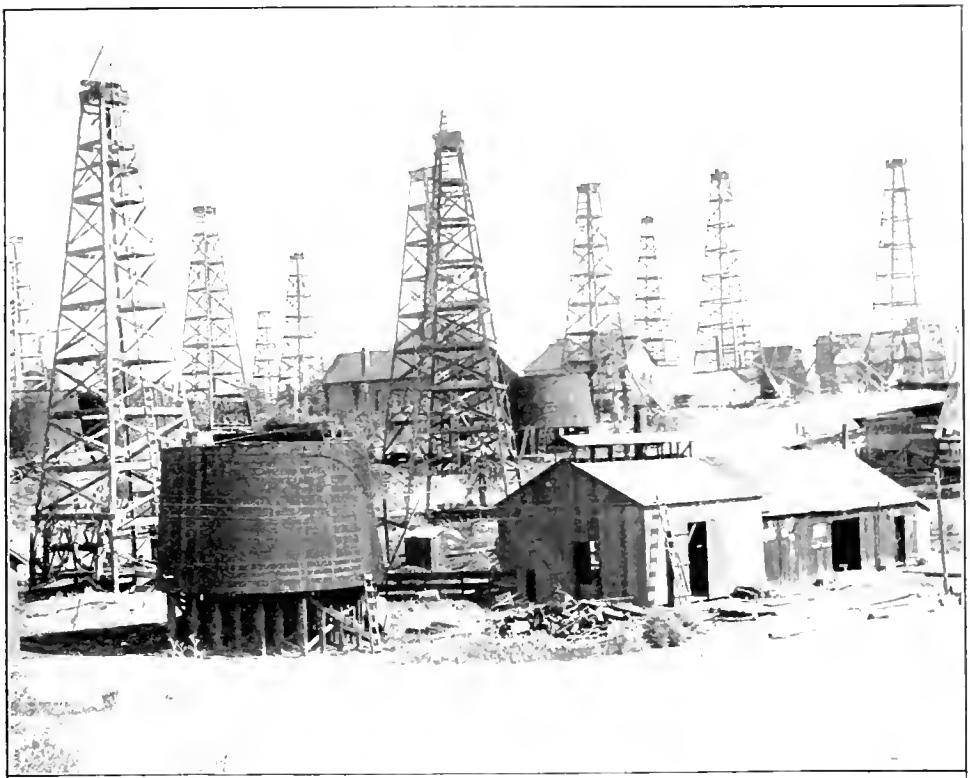
THE CHEMICAL COMPOSITION OF PETROLEUM.

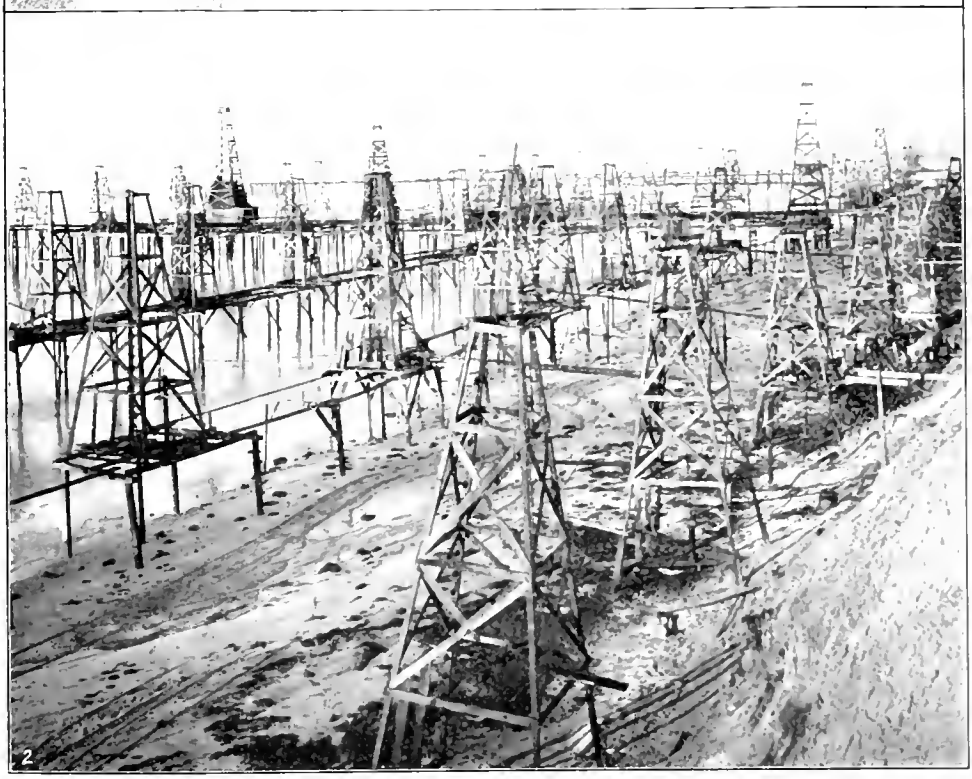
LOCALITY	C	H	O	Specific gravity $H_2O = 1$
	Per cent.	*Per cent.*	*Per cent.*	
Heavy oil, West Virginia	83.5	13.3	3.2	.873
Light oil, West Virginia	84.3	14.1	1.6	.8412
Heavy oil, Pennsylvania	84.9	13.7	1.04	.886
Light oil, Pennsylvania	82.0	14.8	3.2	.816
Parma, Italy	84.0	13.4	1.8	.786
Hanover, Germany	80.4	12.7	6.9	.892
Galicia, Austria	82.2	12.1	5.7	.870
Light oil, Baku, Russia	86.3	13.6	0.1	.884
Heavy oil, Baku, Russia	86.6	12.3	1.1	.938
Java	87.1	12.0	0.9	.923
Beaumont, Texas	86.8	13.2	.....	.920

The gravity of an oil is most commonly expressed in the degrees of the Baumé (B.) scale, on which water has a specific gravity of 10 degrees. The oils from Allegany County, N. Y., run from 38° to 41° B.; from Venango County, Pa., 46° to 48° B.; Warren County, Pa., 43° B.; Lima County, Ohio, 36° to 38° B.; Florence, Colo., 30° B. Russian oils average about 32° B. The lighter oils yield a better quantity of illuminants, while the heavier ones often serve well for lubricating purposes, etc. On exposure to the air many petroleums lose their more volatile constituents and change to a viscous or even solid condition resembling asphalt. The lighter colored varieties are often quite liquid, while the black or dark oils may be slightly viscous. The temperature at which crude petroleum solidifies ranges from 82° F. in some Burma oils to several degrees below zero in certain Italian oils. The flashing point may be equally low in the latter, but in others found on the Gold Coast it rises as high as 370° F. The boiling point likewise shows considerable variation, from 180° F. in some Pennsylvania oils to 338° F. in certain oils found at Hanover, Germany.

DISTRIBUTION OF PETROLEUM. The most noted and most productive field in the United States is the Appalachian, which extends along the western slope of the Appalachian Mountains, from southwestern New York (and eastern Ohio), through western Pennsylvania into West Virginia, Kentucky, and Tennessee. The oil-bearing sandstones are partly Devonian and partly Carboniferous, the latter being especially important in West Virginia. Four fields are recognized in Pennsylvania, the oil varying from amber to dark green. Ohio contains two districts. One of these, the Mecca-Belden field, is of minor importance; a second in eastern Ohio is a westward extension of the West Virginia area. The Lima-Indiana field extends from Lima southwestwardly into Indiana, lying without the Appalachian region as usually defined. The oil here is carried by the Trenton limestone of the Lower Silurian, the depth being about 1300 feet; it was first discovered near Findlay, Ohio. The oil is dark and heavy and resembles the Tennessee and Canada oils in its sulphur contents. Farther south oil is obtained from the Carboniferous in eastern Kentucky and in Tennessee. While new pools are discovered occasionally in the Eastern fields, the most important developments in recent years have been in the Southwestern and Western States.

Oil has been found at a number of localities in the Tertiary rocks of eastern Texas, and several fields, including the Corsicana, Nacogdoches, Beaumont, Elgin, San Antonio, and Sugar Lake, are now being exploited. The first mentioned supplies both light and heavy oils, which are obtained from depths of 950 and 1175 feet respectively. The first well put down in the Beaumont field yielded 75,000 barrels of oil a day, spouting the liquid in a six-inch column to a height of 160 feet; nine days elapsed before the flow was brought under control. The Beaumont oil is a dark asphaltic oil with much sulphur, and is obtained at a depth of 1000 feet. Petroleum has also been discovered in western Louisiana, especially near Jennings, where it is found at a depth of 1800 feet. Southeastern Kansas and northeastern Indian Territory produce some oil from the Cherokee shales and sandstones of the Carboniferous. In Wyoming petroleum occurs in 18 scattered fields, and in formations ranging from the Upper Carboniferous to the Upper Tertiary, but mostly in those of Mesozoic age. The Cretaceous sandstone at Florence, Colo., yields a heavy oil which resembles that of Wyoming in being valuable as a lubricant. Oil has also been obtained in moderate quantities at Boulder, Colo. It is obtained at depths of as much as 2850 feet, and has a gravity of 42.5° B. California contains several oil fields in the southern part of the State. The rocks are of Cretaceous to Neocene age. The oil has an asphaltic base, and is chiefly valuable as a fuel. Petroleum is also known to occur in Washington, Arizona, New Mexico, Montana, and Utah. A moderate amount of oil is obtained from Lambton County, Ontario, at a depth of 400 to 500 feet. Cuba is known to have at





1. OIL WELLS AT LOS ANGELES, CALIFORNIA

2. OIL WELLS ON THE BEACH AT SUMMERFIELD, CALIFORNIA

least small supplies of oil, and a limited quantity has been exported from Porto Rico. In Mexico active exploration has been carried on at several points in the Gulf Coast region with the result of finding supplies of good oil around Tampico. It has an asphalt base. Of the South American countries, Peru is the most important petroleum producer, most of the output coming from the Zorritos field. Petroleum is also said to occur in Venezuela, Argentina, and Ecuador, but it is not taken out of the ground to any extent.

Russia is not only the most important foreign producer of petroleum, but the largest producer in the world, the fields in the Baku region of Southeastern Russia supplying enormous quantities annually. The greater part of the output comes from the Baku field proper, although important quantities are obtained from the Grosni field, 500 miles north of Baku. Rumania contains several promising oil fields, which occur in the same formations as the Russian fields. In Germany oil is obtained near Hanover, and also in Alsace, while some is supplied by the Carboniferous rocks of Great Britain, but does not begin to supply the local demand. In Japan petroleum is obtained on the northwestern coast, and some of it is refined. The crude material sometimes yields 60 per cent. of illuminating and lubricating oils. A high paraffin oil is found in Java, and Sumatra, Borneo, and the Burma field of India are important producers. While petroleum is known to occur in the Philippines, little is obtained, and that by primitive methods; the islands of Panay, Leyte, Guimaras, Negros, Bohol, Mindanao, and Cebú all carry some petroleum.

Mining and Transportation of Petroleum. The modern method of drilling for petroleum is similar to that used in sinking gas and artesian wells. The most prominent feature of the oil-drilling outfit is the derrick, which is a tall, pyramid-like wooden frame about 75 feet high, 12 feet square at the base and about 3 feet at the top. The cost of a rig, as it is called, ranges from $200 to $275. The diameter of the well hole is 10 or 12 inches at the surface, decreasing with depth to 5 or 6 inches. In Russia wells are drilled of much greater diameter, and 26 inches is not an unusual size for the beginning of the bore-hole. In many cases the oil does not flow when the oil-bearing rock is struck, and it is customary in this instance to explode a torpedo at the bottom of the drill-hole, whereupon the oil almost immediately begins to pour out of the well, sometimes with tremendous velocity. For details of petroleum mining, see Well Sinking.

The question of cheap and rapid transportation of crude petroleum from the wells to the refineries is one of great importance. At first the oil was transported on carts, later it was carried in barges or by railway in tank cars, but these methods gave place to the system of pipe lines. At the present day the total length of pipe lines transporting Pennsylvania crude oil is probably over 25,000 miles. The pipes, which have a diameter of from 4 to 8 inches, are usually laid underground and have bends at regular intervals to allow for contraction and expansion. Stations with pumps and storage tanks are placed from 28 to 30 miles apart, the oil being received into the tank at one pumping station and then forced through the pipe to the next one. Since petroleum contains more or less paraffin or wax, much trouble is often experienced in the clogging of the pipes, especially in cold weather, and to clear them out an instrument known as the 'go-devil' is sent through the pipe. This is so constructed that it is forced along by the moving current of oil and scrapes the paraffin off from the inside of the tube. Pipe lines have been built from the Appalachian oil region to Jersey City, Philadelphia, Baltimore, Chicago, and Cleveland.

Refining. The refining of petroleum is based upon the separation of the component hydrocarbons by a process of fractional distillation. This is usually carried out in horizontal cylindrical iron stills, which are surmounted by a dome that connects with a vapor pipe. A common size of still is 30 feet long by 12½ feet in diameter, with a capacity of from 650 to 700 barrels of crude oil. When the latter is placed in the still and subjected to increasing temperature, the oils pass off in the order of their volatility; the separation is not absolutely perfect, however, as oils of lower boiling point may carry over some higher ones. As the vapor rises it passes to the condenser, a series of iron pipes surrounded by cold water. The distillates are led off into their respective tanks. This process of distillation, which is known as the intermittent system, is the one commonly followed in the United States, and the still requires periodic refilling. In Russia a continuous system is employed, involving a series of stills, which are heated to successively higher temperatures. The crude oil then flows slowly from one to the other, and from each one there passes off the product volatilizing at the temperature to which the still is heated.

The process of fractional distillation can be divided into two parts. In the first part of the process the more volatile products, such as gasoline and other naphthas, are evolved. The residue is then transferred to another still in which the second part of the operation is carried on, the oil being heated to a still higher temperature for the purpose of separating the illuminating and lubricating oils. The condensing apparatus ends in the tail house, where the distillates are conducted to their proper tanks. When the various fractions of the distillation are to be kept separate, and of constant composition, a special form of condenser may be used, by means of which the oil is brought into contact with the surface of iron turnings, thereby increasing the evaporation. If the oil contains sulphur it is necessary to redistil it in stills containing copper oxide, which removes the sulphur. *Cracking* is a term used to denote the process of condensing the heavier vapors in the still, causing them to become superheated and decomposed, and thus obtaining a more complete separation of the fractions, as well as increasing the percentage of illuminating oil. In the distillation of the oil the lightest constituents pass off first and the heaviest last. The fractions obtained in the order of their lightness are the following: *Cymogene*. This is the lightest of all, and since its boiling point is 32° F., it is a gas at ordinary temperatures. *Rhigolene*. Boiling point, 65° F. *Petroleum ether*. A highly volatile product having a specific gravity of 0.635. It has sometimes been called Sherwood oil. *Gasoline*. This, properly speaking, is the fraction following petroleum ether, although the name is often applied to a mixture of this and the three previous ones, its gravity thus ranging from 0.635 to 0.690. In

gasoline, or petroleum ether, boiling point ranges from 90° to 200° F. *Naphtha* is a name broadly applied to all light distillates, but more especially to those boiling at 80° to 120° F., and whose gravity varies from as low as 62° B. up to 76° B. *Benzine* (q.v.) represents the least volatile product of the naphthas and has a specific gravity of about 0.73 (57° to 62° B.), and a boiling point of 120° to 150° F. *Ligroine* forms a special grade of solvent naphtha of a specific gravity of 0.715, and a boiling point of 194° to 248° F. Following the lighter naphthas come the illuminating oils, divided into heavy and extra heavy naphthas; in the process of distillation these may either be carried off separately or together. In the former case, the heavy naphthas may be redistilled and separated into benzine and light distillate. The latter may then be mixed with the extra heavy naphthas in varying proportions to form white oil or export oil. There are many grades of domestic illuminating oil or kerosene, which differ chiefly in fire test.

After the naphthas have passed off, the residuum is forced through steam-jacketed filters filled with bone black or fuller's earth; the first portions of the filtrate represent light oils, and are followed by successively heavier ones. When the petroleum belongs to the paraffin group, the residuum is sometimes placed in the tar still for further distillation, and there the heavy vapors are carried over by the aid of superheated steam, the presence of the latter also preventing dissociation of the oil, which if it occurred would be followed by a lowering of viscosity of the lubricating oil and a decrease in the amount of paraffin obtained. The distillates containing the paraffin are freed from the latter by chilling, the effect of this being to cause a separation of the waxy paraffin scales. The oils thus freed from the paraffin are important lubricants, and under this class a number of grades are known as *spindle oil, engine oil, summer dark oil, winter dark oil, cylinder oil, valve oil*, etc. The residue now left in the tar still is a porous mass of separated carbon, solid decomposition products termed coke. The tar is sometimes used without further distillation for the manufacture of vaseline.

Many of the distillates obtained in the treatment of crude petroleum contain acid constituents as well as compounds which in time impart a dark color and unpleasant odor to the distillate. Raw distillates, when used for illuminating purposes, also rapidly char the wick and lose their power of being drawn upward by capillarity. It is therefore customary to purify the various fractions obtained by treatment with sulphuric acid and caustic soda, before they are marketable. The distillate, which has been first cooled to 60° F., is agitated with sulphuric acid in tall cylindrical tanks of wrought iron lined with sheet lead, and known as agitators; about 1½ to 2 per cent. of acid is required. The acid is then washed out with water, and a 1 per cent. solution of caustic soda added, after which a second agitation takes place, followed by washing.

The percentage of the various fractions yielded by different oils varies. Many Pennsylvania oils yield 8 to 10 per cent. naphtha, 70 to 80 per cent. refined oils, 5 to 9 per cent. residuum, and 5 per cent. loss. In the distillation of 100 gallons of crude petroleum there are obtained on the average about 76 gallons of illuminating oil, 11 gallons of gasoline, benzine, and naphtha, and 3 gallons of lubricating oil, while the residuum and loss amount to 10 gallons.

Testing of Refined Oils. Refined oils are usually tested for their color, gravity, flashing and burning points, and sometimes for their behavior when cooled (cold test). The color is determinable by inspection. The gravity is a measure of the purity of the distillate. Too large a proportion of the lighter oils renders the product unsafe for illuminating purposes, while too great a percentage of the heavier oils interferes with its free burning qualities. The gravity test is commonly made by placing the oil in a tall jar and inserting a hydrometer marked preferably with the Baumé scale (water has a value of 10 on this scale). The temperature of oil when this test is made should be 60° F. The fire test includes the determination of the *flashing point*, i.e. the temperature to which the oil must be heated in order to produce a momentary explosion of the mixture of inflammable vapor, and of the *burning point*, i.e. the temperature to which the oil must be heated in contact with the air to take fire and burn on the surface. The burning point is commonly from 6° to 20° C. higher than the flashing point. Kerosene for lighting purposes should have a flashing point of not less than 110° F., and a burning point of not less than 125°. Both the flashing point and burning point are carefully regulated by law in most civilized countries so as to run the minimum risk from explosion. The cold test is of importance for lubricating oils, and is made in order to determine the temperature at which the oil thickens or becomes cloudy. It can be made by cooling the oil in a small tube and noting the temperature at which the oil ceases to flow when the tube is inclined.

Uses. The two chief uses of the distillates from crude petroleum are for illumination and lubrication, but the various fractions in many cases have special applications. Rhigolene is used as a local anæsthetic; petroleum ether is employed as a solvent for caoutchouc, fatty oils, and plant principles, and for carbureting air in gas machines; gasoline is employed in the extraction of oil from oil seeds, in carbureting coal gas, in gasoline lamps, stoves, and plumbers' lamps. Naphthas in general are employed as solvents for resins in varnish-making, and in the manufacture of oilcloth. Boulevard gas fluid is a product of 0.68 specific gravity used in street lamps, while benzoline is a deodorized naphtha of 0.70 specific gravity. Benzine is employed for dry cleaning, as a substitute for and adulterant of turpentine for cleaning printer's type, and for dyers' and painters' use. The benzine of the U. S. Pharmacopœia has a specific gravity of 0.67 to 0.77, and a boiling point of 122° to 144°, and therefore represents a higher distillate. Astral oil and mineral sperm oil are special illuminating oils of high flashing points. Crude petroleum is much used for fuel purposes in engines. Along the Pacific Coast, especially in southern California, where good coal is scarce, the locomotives consume large quantities of crude oil. Paraffin residue is placed on the market for medicinal purposes under the name of vaseline, petroleum ointment, and cosmoline. It is also used in the manufacture of chewing gum, and for insulating purposes in electric work.

Production. The growth of the petroleum industry in the United States is shown in the fol

lowing table, which gives the annual production at intervals from 1859 to 1900:

YEAR	Barrels
1859	2,000
1860	500,000
1865	2,497,700
1870	5,260,745
1875	10,926,945
1880	26,286,123
1885	21,858,785
1890	45,823,579
1895	52,862,276
1900	63,620,529

The production of crude petroleum in the United States in 1901 amounted to 69,389,194 barrels, valued at $66,417,335. Of this quantity, 48.45 per cent. came from the Appalachian field, 31.61 per cent. from the Lima-Indiana area, and 19.94 from the other areas combined. The number of gallons of petroleum and its derivatives exported in 1901 was 1,062,750,306, valued at $71,479,124. This went to all parts of the world, but chiefly to Europe. In this same year the quantity of manufactured petroleum exported by Russia was 36.8 per cent. of that exported by the United States. New York is the leading port of exportation, with Philadelphia second. So large has the export trade become that some countries have a large fleet of specially constructed tank steamers engaged in the oil-carrying trade. Up to 1899 the total tonnage of these was nearly 400,000 tons. The world's production of petroleum in 1901 was as follows:

	Barrels
United States	69,389,194
Russia	85,168,556
Galicia	3,251,544
Sumatra, Java, Borneo	3,038,700
India	1,430,716
Rumania	1,106,460
Canada	704,872
Japan	600,000
Germany	313,630
Peru	72,761
Italy	10,100

PETROL'OGY (from Gk. πέτρα, *petra*, rock + -λογία, *-logia*, account, from λέγειν, *legein*, to say). PETROGRAPHY. LITHOLOGY (obsolescent). The science which treats of the materials of the stony portion of the earth (the lithosphere), and of meteoritic bodies. Petrography is the purely descriptive division of the science, but in general usage it has the same scope as petrology. Petrology, or petrography, is one of the geological

science and ... the same rank as mineralogy. It concerns itself chiefly with the composition (chemical and mineralogical), textures, origin, and alterations of the rocks; and its methods are largely those of chemistry, mineralogy, and physical optics. It is one of the newest of the sciences and may be said to have had its birth in 1862, when Sorby and Zirkel succeeded in preparing transparent rock sections and adapting the microscope to their study. Consult: Harker, *Petrology for Students* (Cambridge, 1895); Teall, *British Petrography* (London, 1888); Zirkel, *Lehrbuch der Petrographie* (2d ed., Leipzig, 1894); Rosenbusch, *Elemente der Gesteinslehre* (Stuttgart, 1898); id., *Mikroskopische Physiographie der Mineralien und Gesteine* (3d ed., ib., 1896; first volume translated by Iddings, under title, *Microscopical Physiography of the Rock-Making Minerals*, 4th ed., New York, 1900). See ROCK.

PETRO'NIUS, GAIUS. A Roman voluptuary at the Court of Nero, whose profligacy is said to have been of the most superb and elegant description. We know, however, very little about him. He was at one time proconsul of Bithynia, was subsequently appointed consul, and is said to have performed his official duties with energy and prudence. But his grand ambition was to shine as a Court exquisite. He was intrusted by his Imperial master and companion with the charge of the royal entertainments, and thus obtained (according to Tacitus) the title of *Arbiter Elegantiæ*. The influence which he thus acquired was the cause of his ruin. Tigellinus, another favorite of Nero, conceived a hatred of Petronius, brought false accusations against him, and succeeded in getting his whole household arrested. Petronius saw that his destruction was inevitable, and committed suicide, A.D. 66, but in languid and graceful style, such, he thought, as became his life. He opened some veins, but every now and then applied bandages to them, and thus stopped the flow of blood, so that he was for a while enabled to gossip gayly with his friends, and even to appear in the streets of Cumæ, before he died. We are told that he wrote, sealed, and dispatched to Nero, a few hours before his death, a paper containing an account of the tyrant's crimes and flagitious deeds. Petronius is generally believed to have been the author of a very remarkable ancient romance, or satire, which has survived in part under the name of *Petronii Arbitri Satyricon*, an extensive work of fiction, of which fragments and a long episode entitled *The Supper of Trimalchio* (*Cena Trimalchionis*) were discovered in the seventeenth century and published at Paris in 1664. As a description of one phase of life in the first century of the Christian Era the work is invaluable, while to the student of Latin it offers the best example of the colloquial language of the time. The exaggerated picture of the vulgar society of a *nouveau riche* is often disagreeable, but always amusing. The scene is laid in some small but fashionable town of Campania, perhaps Baiæ or Puteoli probably under Nero, or shortly before. The standard text is that of Büchcler (Berlin, 1862, with a smaller edition (Berlin, 1895). There is also edition of the *Cena* episode alone, with German translation and commentary, by Friedländer (Leipzig, 1891), and an edition with introduction and commentary by Waters (Boston, 1901). All or the greater part were translated into English by Kelly (London, 1856); and there is a recent and very sympathetic translation of the *Cena*, with an excellent introduction, by Peck (New York, 1898). For the vocabulary of Petronius, see the *Lexicon Petronianum* of Segebade and Lemmatzsch (Leipzig, 1898). Compare, also, Collignon, *Etude sur Pétrone* (Paris, 1892).

PETROPAVLOVSK, pyĕ'trô-pâv-lôfsk'. A district town in the Territory of Akmolinsk, West Siberia, situated on the Ishim and the Trans-Siberian Railway, 191 miles west by rail from Omsk (Map: Asia, F 3). Tallow and leather are the chief products; there is a considerable trade in animals, animal products and manufactures, with the native tribes. Population, in 1897, 20,014.

PETROPAVLOVSK. The chief town of Kamtchatka (q.v.).

PETROPOLIS, pā-trō'pō-lēs. The capital of the State of Rio de Janeiro, Brazil, situated in a mountainous region about 20 miles north of Rio de Janeiro (Map: Brazil, J 8). It was formerly the summer residence of the Imperial Court, and contains a palace, a number of magnificent villas, hotels, and parks. The place was first colonized by Germans in 1845, and a considerable portion of its present population is of German origin. It was made the capital of the State in 1894. Population, in 1898, estimated at 12,000.

PETROVSK, pyĕ-trôfsk'. Capital of a district in the Government of Saratov, Russia, 93 miles northwest of Saratov (Map: Russia, G 4). The manufacture of flour and butter is extensively carried on. Population, in 1897, 13,200.

PETROVSKOYE, pyĕ-trôf'skoi-*e*. A village in Russia. See BUTURLINOVKA.

PETROZAVODSK, pyĕ'trô-zä-vôtsk'. The capital of the Government of Olonetz, Russia, situated on the western shore of Lake Onega, about 190 miles northeast of Saint Petersburg (Map: Russia, D 2). It has a gymnasium, a theological seminary, and a famous Government cannon foundry. The town grew up around an iron foundry established in 1703 by Peter the Great. Population, in 1897, 12,965.

PETRUCCI, pā-trōō'chē, OTTAVIANO DE' (1466-1539). The discoverer of the art of printing music with movable types. He was born at Fossombrone, near Urbino (Lat. *Forum Sempronii*, from which Petrucci adopted the name *Petrutius Forosempronensis*). The Council of Venice gave him a monopoly of his invention for twenty years (1498-1518), and from 1501 to 1511 he developed his discovery with profit to himself, but finally attempted experiments that proved too costly and so was compelled to sell his privilege and business to Amadeo Scotti and Niccoli da Rafael, upon which he returned to his native town. Securing a privilege for the Papal States for a term of fifteen years, he commenced work again in his home town, but with very much inferior results. Petrucci prints are exceedingly rare, and are very valuable. They are remarkable for their neatness of execution and correctness.

PETRUCHIO, pā-trōō'kē-ō. The husband of Katharine in Shakespeare's *Taming of the Shrew*. In taming his spoiled, headstrong wife, he resolves "to kill her in her own humor," and storms like a madman, thwarting all her wishes, yet

never losing his good humor, and at last conquering her.

PETTENKOFEN, pĕt'ten-kō'fen, AUGUST VON (1822-89). An Austrian genre and military painter, born in Vienna. He had been a cavalry officer, and several of his pictures represent military scenes. He also treated subjects from the peasant life of Hungary, often in its brighter aspects. His works include "Hungarian Artillery on the March"; "The Ambulance Wagon" and "Hungarian Volunteers," both owned by Mrs. W. H. Vanderbilt, New York City; "A Rendezvous" (1867), Vienna Museum; and "A Woman Spinning." He was made a member of the Vienna Academy in 1866, and of the Munich Academy in 1867, and was knighted in 1876.

PETTENKOFER, pĕt'ten-kō'fĕr, MAX VON (1818-1901). A celebrated German chemist and hygienist, born in Bavaria. He studied medicine and chemistry at Munich, and later under Liebig at Giessen. In 1847 he became professor of medical chemistry at Munich. His famous researches formed the foundation of the science of experimental hygiene. At his instance chairs of hygiene were founded at the Bavarian universities, and he himself accepted the professorship at Munich in 1865. He became co-editor of the *Zeitschrift für Biologie* in 1864, and was for years one of the editors of the *Archiv für Hygiene*, which he founded in 1883. In recognition of his services to science, many honors were bestowed upon him, and in 1889 he was chosen president of the Bavarian Academy of Sciences. Pettenkofer carried out a number of interesting and useful investigations in chemistry. He is best known, however, for his experimental researches on the ventilation of dwellings, on respiration and the metabolic assimilation of food, and on cholera. The researches on metabolism were carried out, jointly with Karl Voit, by the use of an apparatus of Pettenkofer's invention, which permits the determination with great precision of the amount of atmospheric oxygen used up by the body and the amount of carbonic acid and water-vapor given off. As to cholera Pettenkofer was the first to show: that the symptoms of that disease are caused by the activity of a specific germ, which may be disseminated through ground-water; that the spread of the disease is dependent to a great extent on local climatic and sanitary conditions; and that infection is due largely to individual predisposition. Most of his contributions appeared in the *Zeitschrift für Biologie*, mentioned above. He published besides: *Untersuchungen über die Verbreitungsart der Cholera* (1855); *Ueber den Luftwechsel in Wohngebäuden* (1858); *Zum gegenwärtigen Stand der Choleralrage* (1887), etc. His *Beziehungen der Luft zu Kleidung, Wohnung und Boden; Was man gegen die Cholera thun kann; Populäre Vorträge*, and other works, have passed through several editions.

PETTIE, pĕt'i, JOHN (1839-93). An English painter, born at East Linton, Haddingtonshire. He studied under Lauder at the Trustees' Academy in Edinburgh. Afterwards he lived in London, and for a while had a studio with Orchardson. His figures are usually in the costume of the sixteenth or seventeenth century. His compositions are animated and pictorial, and his color schemes are rich and well handled. His works include: "Edward VI. Signing a Death Warrant" (1879, now at Hamburg); "The Body Guard"; "A Challenge"; and "The Chieftain's Candlesticks." He was elected to the Royal Academy in 1873.

PETTIGREW, JAMES BELL (1834—). An English physiologist, born at Roxhille, Lanarkshire. He was educated at Glasgow University, studied medicine at Edinburgh, and, after acting as Croonian lecturer to the Royal Society (1860), as assistant curator of the Hunterian Museum in London (1862-68), and as curator of the Edinburgh Museum of the Royal College of Surgeons, became lecturer on physiology at Edinburgh (1873), and Chandos professor of medicine and anatomy at Saint Andrews (1875). Pettigrew made a special study of organic muscles, and, with the purpose of analyzing the problem of the flying machine, of the wings of insects, bats, and birds. His writings include *Animal Locomotion* (1873), and many contributions to scientific journals.

PETTIGREW, JAMES JOHNSTON (1828-63). An American soldier, born in Tyrrell County, N. C. He graduated at the University of North Carolina in 1847, and was appointed by President Polk assistant professor in the Naval Observatory. In 1848 he resigned, to study law. He visited Europe in 1850 and for a time acted as secretary of the Spanish Legation. In 1852 he returned to the practice of law in Charleston, and was a member of the Legislature in 1856. He joined the Sardinian Army in 1858, but the armistice of Villafranca destroyed his hopes of active service. After a visit to Spain he returned to Charleston to practice law, and was prominent in militia affairs. He took part in the first operations of the war at Castle Pinckney and Morris Island, and in May, 1861, was made colonel of the Twenty-second North Carolina Regiment. In the spring of 1862 he was promoted to brigadier-general, and assigned to the Peninsula. He was wounded and captured at Seven Pines (May 31st), and after exchange was assigned to command a new brigade of North Carolinians at Petersburg. In the fall of 1862 he made an unsuccessful attempt to recapture Newbern, N. C., and he opposed Stoneman before Richmond early in 1863. At the battle of Gettysburg (July 1st-3d) his brigade, a part of Heth's division, A. P. Hill's corps, opposed the famous Iron Brigade the first day and lost one-third of its numbers. One regiment, the 26th North Carolina, lost in killed and wounded 584 out of 820. On the third day he commanded Heth's division. In the famous charge on Cemetery Ridge this division formed the left of the assaulting force. Owing to a sharp change in the direction of the stone wall, at the 'Bloody Angle,' which made it 80 yards farther from the Confederate lines, it has been officially shown that men of this division went at least 40 yards farther up the hill than those of Pickett's. Pettigrew's brigade had left 935 men and was commanded by a major, the only field officer left. On the retreat he was mortally wounded by Federal cavalry at Falling Waters, July 14th, and died at Bunker Hill, Va., July 17th. For his part in this battle consult *North Carolina Regiments, 1861-65*, vol. v., published by the State (1901).

PETTY, Sir WILLIAM (1623-87). An English political economist, born at Romsey, in Hampshire. After studying at the Jesuit College at Caen, in Normandy, he returned to England and

entered the Royal Navy. On the outbreak of the Civil War he retired to the Continent and studied at Utrecht, Amsterdam, Leyden, and Paris. He returned to England and took the degree of doctor of physic at Oxford in 1649, and was soon after appointed fellow of Brasenose College. In 1651 he became professor of anatomy, and in 1652 was appointed physician-general to the army in Ireland. His intimacy with Henry Cromwell and other members of the Cromwellian party involved him in the downfall of the Protectorate, but he soon won the confidence of Charles II. He was one of the founders of the Royal Society, which was incorporated in 1662. He was one of the authors of *Natural and Political Observations*, published in 1662, which was the first book on vital statistics ever written. Ten years later his *Political Anatomy of Ireland* appeared. His later works were: *Quantulumcunque Concerning Money* (1682); *Observations upon the Cities of London and Rome* (1687); and a number of *Essays in Political Arithmetick*, published between 1683 and 1690.

PETTY BAG OFFICE. An office attached to the Court of Chancery in England, prior to 1874, for the care of suits for and against solicitors and officers of the court; for all judicial matters relating to statutes, recognizances, writs of *scire facias* and other writs, and certain other matters relating to the Crown. The name was derived from the custom of keeping the writs and returns in a little sack or bag (*in parvâ bagâ*). A great deal of miscellaneous business was also transacted in the Petty Bag Office, which the Lord Chancellor and Master of the Rolls were empowered to regulate and transfer from time to time. When the jurisdiction of the Court of Chancery was transferred to the High Court of Justice by the Judicature Acts in 1874, the office of the clerk of the petty bag was abolished, and his duties and powers are now vested in the senior clerk of the Crown Office department of the Central Office.

PETTY-FITZMAURICE, pĕt'tĭ-fĭts-mą'rĭs. See SHELBURNE.

PETTY OFFICER. A term applied in the navy to the men of the enlisted force who are appointed to position below the rank of warrant officer; these positions or 'ratings' correspond to the non-commissioned grades of the army, but they are much more numerous. The rates of pay are from $30 to $70 per month. (See section on *Navy*, under UNITED STATES.) The most capable and deserving petty officers are promoted to warrant rank as vacancies occur in the grades of boatswain, gunner, and carpenter; and, if exceptionally meritorious and well informed, they may then be commissioned ensigns in the regular line of promotion, but not more than twelve may be commissioned in any one year.

PETTY SESSIONS. An English court, constituted by two or more justices of the peace, or a borough magistrate, when sitting for the trial of certain minor criminal cases, or for the preliminary hearing and commitment for trial of persons accused of graver crimes, which can only be tried at Quarter Sessions. The jurisdiction of the justices in Petty Sessions is mainly over violations of certain special acts, such as those concerning poaching, vagrants, bastardy proceedings, absconding workmen, apprentices, poor laws, etc. One of the important functions of this court is to hear charges for all indictable offenses, and to commit the accused person for trial at Quarter Sessions, if a probable case is made out against him. The jurisdiction of Petty Sessions and Special Sessions is practically the same, except that the latter court is only held on special notice. Appeals from Petty Sessions are heard in the Court of Quarter Sessions. See JUSTICES OF THE PEACE; SPECIAL SESSIONS; QUARTER SESSIONS.

PETU'NIA (Neo-Lat., from Brazilian *petun*, tobacco). A genus of plants of the natural order Solanaceæ, natives of South America, and during the nineteenth century introduced into cultivation in other countries for their beautiful flowers. Although naturally perennials, they are generally cultivated as garden annuals. The slightly viscid foliage emits a peculiar, often disagreeable odor, especially in the evening or during stormy weather. The common garden petunias are mostly hybrids of *Petunia nyctaginiflora* and *Petunia violacea*, which themselves are not frequently cultivated. *Petunia nyctaginiflora* is a stout species with white flowers; *Petunia violacea*, a trailing plant with purplish violet blossoms. The number of varieties is very large and includes single and double flowered forms, plain or variegated, with innumerable variations in color from pure white to deep violet, through rose, purple, pink, and many other shades. The finest flowers are produced on deep rich soils in sunny situations. They are well adapted for beds and borders and are also grown as house and conservatory plants. Since seedlings do not come true to the parent plant, the choice varieties are propagated by cuttings. These are put in sandy soil with bottom heat in August, potted singly after they have rooted, wintered in the greenhouse, and set out in the open in late spring.

PEUCER, poi'tsĕr, KASPAR (1525-1602). A German scientist and scholar, son-in-law of Melanchthon. He was born at Bautzen and studied at Wittenberg, where he was made professor of mathematics in 1554 and of medicine in 1560. But in 1574 he was removed from his position as rector of the university, because of his intimate relations with Crypto-Calvinists. After twelve years' imprisonment, Peucer was freed and became Court physician to the Prince of Anhalt. He wrote on astronomy, geometry, and medicine, and edited some of Melanchthon's letters (1565 and 1570). Consult Henke, *Kaspar Peucer und Nikolaus Crell* (Marburg, 1865).

PEUERBACH, poi'ĕr-bâḥ, **PURBACH,** or **PEURBACH,** GEORG VON (1423-61). An Austrian mathematician and astronomer, born at Peurbach, near Linz. He studied in Vienna, and afterwards traveled in Germany, France, and Italy, where he delivered astronomical lectures at Ferrara, Bologna, and Padua. In 1454 he was astronomer to King Ladislas of Hungary, and somewhat later professor at the University of Vienna, and with Regiomontanus one of the leaders in mathematical thought in his century. Peuerbach compiled a table of sines, taking $60 \cdot 10^4$ for unity or the length of the radius, and thus prepared the way for decimal fractions. The table was completed after his death by his pupil Regiomontanus. Peuerbach also calculated new tables of the planets, and gave a new list

of the fixed stars. He wrote: *Tractatus Super Propositiones Ptolemæi de Sinibus et Chordis* (1541); *Theoricæ Novæ Planetarum* (1542); *Sex Priores Libri Systematis Almagesti* (1496, 1550); *Institutiones in Arithmeticam* (1511); *Tabulæ Eclipsium* (1514). With Regiomontanus he wrote an *Epitome in Cl. Ptolemæi Magnum Compositionem* (1543). Consult: Schubert, *Peuerbach und Regiomontanus* (Erlangen, 1828); Fiedler, *Peurbach und Regiomontanus, eine biographische Skizze* (Leobschütz, 1870).

PEUTINGER, poi'ting-ẽr, KONRAD (1465-1547). A German antiquary, born at Augsburg. He studied law at Padua, and at twenty-eight became syndic of his native city, which he represented in several Diets, notably that of Worms in 1521. His writings on classical antiquities were very valuable; the most important is *Inscriptiones Romanæ* (1520). He is best known as owner of the *Tabula Peutingeriana*. Consult the reproduction edited by Mannert (Ravensburg, 1888), and Herberger, *Konrad Peutinger in seinem Verhältnis zu Kaiser Maximilian* (Augsburg, 1851).

PEUTINGERIAN TABLE (Lat. *Tabula Peutingeriana*). The name given to a most interesting ancient document, which exhibits the military roads of the Roman Empire and of the world known to the Romans. It is not, properly speaking, a map, no regard being paid to geographic position or the extent of countries. The great lines of road are laid down in a narrow strip, as if nearly parallel, all proceeding from Rome as a centre; and as to rivers, it only appears whether they cross the road from left to right or from right to left of the traveler proceeding from Rome. The Mediterranean and other seas are represented by mere narrow channels. A small house is the mark for a town; important towns and military stations are distinguished by walls and towers. Rome, Constantinople, and Antioch are each represented by a circle, within which is a human figure seated; in the case of Rome the figure is crowned. Until very recently a portion of the only copy of this valuable relic of antiquity known to exist was evidently wanting, as it terminated abruptly on the west at the confines of Spain, and included only the eastern parts of Britain. In the east it traces roads through India to a number of places of trade as far as the mouths of the Ganges. It is on parchment, and, as described in all the publications devoted to it, 21 feet in length, and about one foot wide. The extant document seems to be a thirteenth-century copy of an original made in the third century. It was found in the library of the Benedictine monastery at Tegernsee, in Upper Bavaria, in the fifteenth century, by Konrad Celtes, who bequeathed it to Konrad Peutinger of Augsburg, a zealous antiquary, and one of the earliest writers on the Roman and other antiquities of Germany. Peutinger began to prepare a copy of it for publication, but died before he could accomplish his purpose, which, however, was partially executed by Mark Welser, in his *Fragmenta Tabulæ Antiquæ ex Peutingerorum Bibliotheca* (Venice, 1591). The ancient document itself remained in the hands of the Peutinger family, and attracted no further notice till it was offered for sale in 1714, and purchased by Prince Eugene, who presented it to the Imperial Library of Vienna, in which it still remains. An exact copy of it was published at Vienna in 1753, with an introduction and index by F. C. von Scheyb. It was again published as an appendix to Katancsich's *Orbis Antiquus* (Budapest, 1825); and at the request of the Academy of Munich, a revised edition was published by Konrad Mannert (Leipzig, 1824). Since that time a leaf detached from the sheets forming the map has been found in the Imperial Library at Vienna. See Miller's edition of the same (Ravensburg, 1888), and a colored facsimile by Desjardins (Paris, 1869-71).

PEV'ERIL OF THE PEAK. A novel by Sir Walter Scott (1823). It is a story of the Popish Plot in the reign of Charles II., in which the hero, Julian Peveril, becomes involved because of his connection with the Countess of Derby, the family estate being near the Peak of Derbyshire.

PEW (OF. *pui, puy, poi, pu*, elevated place or seat, hill, mound, *puy*, elevated railed balcony or gallery, from Lat. *podium*, balcony, from Gk. *πόδιον*, diminutive of *πούς, pous*, foot). An inclosed seat in a church, appropriated to a person or family. Such seats were in use in English churches some time before the Reformation. They were originally plain fixed benches, with partitions of wainscoting about three feet high, and sides of the width of the seat, paneled or carved. In the later Reformation period and probably under the influence of the Puritans, who, objecting to some parts of the service which they were compelled to attend, sought means to conceal their non-conformity, pews grew into large and high inclosures, containing from two to four seats, and fitted with doors, desks, and cushions. At first pews seem to have been assigned only to the patrons of churches, but gradually the system of appropriation was extended. It would appear by the common law of England that every parishioner has a right to a seat in the church, and that the churchwardens are bound to provide for each one as best they can. So, also, by the common law, the right to a pew is only a right to use it for the services of the church, and at times when it is open for use, subject to the regulations of the church; and there is no right of access to it for any other purpose except repairs. In the United States pews are sometimes the property of the church congregation and sold or rented for them, or they are individually owned or leased on perpetual leases subject to a ground rent. Whether property in pews is real or personal now depends in many States upon the provisions of the statute law. The right of property in the pews of a church vests in the trustees, while the right of use and occupation at all customary times is in the purchaser or lessee, and the latter may maintain an action on the case for a disturbance of this right.

PEW RIGHTS. By the early common law, a person could not obtain strictly legal rights to a church pew. However, at a later date it was recognized that a legal right to a pew could be acquired, which would be protected by the common-law courts. Finally, exclusive pew rights, when purchased by the pewholder, were considered as incorporeal rights or interests in the real property, subject to the superior right of the trustees or church corporation to deal with the building as might seem best for the interests of the church. For example, the church trustees could rebuild the church, or sell it and rebuild

on another site, without making compensation to the pewholders. In such cases, however, by the weight of authority, a pewholder would be entitled to a pew of like character in the new edifice. However, if the church corporation is dissolved, the pewholders are entitled to have the value of their pew rights returned out of the church funds. A pewholder has practically no more substantial rights under a sale to him of the pew than under a perpetual lease, as he cannot in any event change the character of the pew as to decorations, etc., and cannot prevent the church authorities from making alterations, etc. The common law above set forth prevails in most of the United States. A few States have passed statutes expressly making pew rights real property, and in others the statutes define such rights as personal property. In most churches, however, pews are let from year to year by a sort of verbal lease, and the pewholders merely have temporary possessory rights. Consult Phillimore, *Ecclesiastical Law of the Church of England* (2d ed., London, 1895); and the authorities referred to under Real Property.

PEWEE (onomatopoetic name). Any of several small olive-green or brown American tyrant flycatchers (q.v.). The common pewee or phœbe-bird (*Sayornis Phœbe*) measures about 12 inches across the extended wings. It is brown on the back, darker on the head, with a yellowish-white breast and belly, quills brown, slightly edged with a lighter color. Its principal habitat is the Middle and Atlantic States. It comes north in April, and usually hatches a brood by the middle of May and another by the first of August. In October it returns to the south, migrating at night. It placed its nest originally on a ledge of rocks, or plastered it bracket-like against the surface of a mossy cliff, but now more frequently chooses a beam or ratter of a building or bridge. The nest is made of mud, grass, mosses, and the like, and is lined with down and other soft materials; but these materials seem so favorable for the breeding of parasites that the second brood is often raised in a new nest. It lays from four to six eggs, white, rarely with a few reddish spots at the larger end. The hatching takes about thirteen days, and in a few days more the young birds leave the nest. The pewee occurs as far west as eastern Nebraska. Its food consists wholly of insects, captured usually on the wing. Its plaintive note, *phœbe*, is well known. Two allied species, Say's pewee (*Sayornis Sayi*) and *Sayornis nigricans*, occur in the Western States. The former is grayish-brown, with cinnamon belly and black tail, while the latter is blackish, with a white belly.

The very familiar wood pewee (*Contopus virens*) measures from 10 to 11 inches across the outspread wings, with the color of the back much like that of the phœbe-bird, but it has two pale grayish bands across the wings, a narrow whitish circlet around the eyes, a greenish-yellow belly, and grayish throat and breast. Its flight is rapid, with sudden sweeps when darting after its insect prey, which it pursues in the shade of the orchard or woods. Its note is much slower and more plaintive than that of the phœbe and is more frequently single-syllabled. It comes north two or three weeks later than the phœbe, going as far north as New Brunswick and Nova Scotia, and retreating as far south in the winter as New Granada. The nest is saddled upon the branch of a tree and is notable for the skill with which it is covered with lichens, so that it very closely resembles a natural wart on the limb. The eggs are four or five, light yellowish, with reddish and lilac spots at the larger end. The pewee is very courageous, defending its nest against all intruders. Two broods are raised where the season is long enough. The Western wood pewee (*Contopus Richardsonii*), which resembles the 'wood pewee' except in being darker and in having shorter legs, longer wings, and larger feet, is found from the sixtieth parallel of latitude to Panama and from the great plains to the Pacific.

The least pewee (*Empidonax minimus*) is a small bird, present in every village garden and roadside, and the type of a genus containing several small similar species. It makes a neat nest of hempen materials placed in the crotch of a small tree. Consult general works on American ornithology. See Plate of Typical Flycatchers with the article Flycatcher; and Colored Plate of Eggs of American Song-Birds.

PEWIT. A British name for several birds having a cry more or less resembling these syllables, especially the lapwing and certain gulls.

PEWTER (OF. *peutre, peautre, piautre*, Fr. *peautre*, probably a variant of OF. *espeautre*, pewter, from LGer. *spialter*, Eng. *spelter*, zinc). An alloy of tin and lead, of which there are principally three varieties: *Ley* or *common pewter*, consisting of tin, 4 parts, and lead, 1 part; *plate pewter*, consisting of tin, 90 parts, antimony, 7, bismuth, 2, and copper, 2; and *trifle pewter*, consisting of tin, 79 parts, antimony, 15, and lead, 6. Pewter is a soft metal, similar in appearance to tin, but somewhat duller and darker in color. It was formerly extensively used for making plates, teapots, and other domestic utensils, but, on account of the poisonous character of the lead, prohibitory measures have been adopted by the governments of several countries, and consequently other alloys have largely taken its place. Old pewter, however, is now highly prized by collectors of antiques. See Alloy.

PEYER'S GLAND. One of the glands forming aggregations of solitary lymphoid follicles, first discovered by Johann Konrad Peyer, principally found in the *ileum*, the lower division of the small intestine, and connected with the function of absorption. (See Digestion.) The solitary glands which are not aggregated have essentially the same structure as those which make up the patches of Peyer, or Peyer's glands.

PEYOTE, pā-yō'tā (Sp., from Aztec *peyotl*, caterpillar, in allusion to the downy growth upon the root of the southern variety). The Mexican name given to several species of plants used by the Indians of the plains and central plateau to produce a peculiar kind of mental exhilaration. The practice existed among the native tribes from the Arkansas River as far south at least as the City of Mexico, and in a few places had crossed the main divide to the Pacific Coast. The southern plant, to which the name was originally applied by the Aztecs, is a species of Compositæ, the active principle being in the root. The variety best known, and the use of which is everywhere found from about the Valley of Mexico northward to the Arkansas, is a small cactus, botani-

eally identified as *Lophophora Williamsii*. The plant grows abundantly in a wild state along the Rio Grande and southward, and is gathered by the Indians, who use either the dried top in its raw state, or the whole plant, sliced, in decoction. It is taken at intervals during a ceremony which lasts throughout the night. The effect is to exhilarate and intensify the imaginative faculties, producing a pleasant dreaminess, without, however, overmastering the will power or producing a disagreeable reaction later. The Indians regard it as the embodiment of a vegetable god, and prize it, aside from its regular ceremonial purpose, as a specific in numerous diseases and ailments, particularly in the relief of fevers and hemorrhages. Certain prepared forms have been put upon the market by a leading drug manufacturer.

PEYRÈRE, pā'rār'. Isaac de la. See Preadamites.

PEYRON, pā'rōn'. Vittore Amadeo (1785-1870). An Italian philologist, born at Turin. He studied under the Abbé Valpergo di Caluso, and in 1815 succeeded him as professor of Oriental languages at Turin. He translated Thucydides into Italian, edited *Fragmenta Ciceronis Orationum* (1824) and other classical texts, and was a member both of the Turin Academy of Sciences and of the French Institute. It was he who first placed the study of Coptic upon a scientific basis by the *Lexicon Linguæ Copticæ* (1835; new ed. 1896), with the supplemental *Grammatica Linguæ Copticæ* (1841).

PEYRONNET, pā'rō'nā'. Charles Ignace, Count (1778-1854). A French politician, born at Bordeaux. As an advocate in his native town he displayed great zeal for the cause of the Bourbons during the decline of Napoleon's power. In 1815 he was made president of the Court of First Instance at Bordeaux and later became Procurator-General at Bourges. In 1821 he was elected to the Chamber of Deputies and in the same year was named Minister of Justice—a post which he held till 1828. He was one of the most prominent champions of reaction during this period, his term of office being marked by the enactment of a rigorous press law (1822), the passage of the iniquitous law against sacrilege (1825), and the reëstablishment of the censorship. In May, 1830, he became Minister of the Interior under Polignac and in that capacity signed the famous Ordinances which brought about the July Revolution (q.v.). Peyronnet fled, but was arrested at Tours and condemned to imprisonment for life on the charge of treason. He was pardoned in 1836. During his captivity he wrote *Pensées d'un prisonnier* (1834) and *Histoire des Francs* (1835).

PÉZENAS, pāz'nâs'. A town in the Department of Hérault, France, on the Hérault, 25 miles west-southwest of Montpellier (Map: France, K 8). It manufactures spirits, wine, and cognac, and the prices which prevail at its weekly market of these articles are registered throughout Europe. Population, in 1901, 7073.

PEZZA, pād'zâ. Michele. The real name of the Italian brigand commonly known as Fra Diavolo (q.v.).

PFÄFERS, pfā'fērs, or **PFEFFERS.** A village in the Canton of Saint Gall, Switzerland, situated near the Tamina River about 2½ miles southwest of Ragatz (Map: Switzerland, D 1). It is noted for its hot springs, which rise a short distance from the village in the gorge of the Tamina. The water, varying in temperature from 99° to 102° F. and containing in small proportions carbonate of lime, chloride of sodium, and magnesia, is used for bathing, and has considerable curative qualities. The springs of Pfäfers were known as early as the thirteenth century, and the present Kurhaus was erected at the beginning of the eighteenth century to replace the older buildings dating from the fifteenth and seventeenth centuries. The baths belonged formerly to the Benedictine monks and were acquired by the canton in 1838. The permanent population of the village is about 600.

PFAFF, pfäf. Johann Friedrich (1765-1825). A German mathematician, born at Stuttgart. In 1788 he became professor of mathematics in Helmstedt, and in 1810 at Halle. He invented a method of integrating partial differential equations of the first order in any number of variables, which depends on the solution of the general problem of integrating a linear homogeneous equation between the differentials. Equations of this kind are therefore called Pfaffian equations and their integration is called the Pfaffian problem.

A determinant,

$$\begin{vmatrix} a_{11} & a_{12} \ldots\ldots\ldots\ldots a_{1n} \\ a_{21} & a_{22} \ldots\ldots\ldots\ldots a_{2n} \\ a_{n1} & a_{n2} \ldots\ldots\ldots\ldots a_{nn} \end{vmatrix}$$

in which $a_{ij} = -a_{ji}$, is called a *gauche*, or *skew* determinant; if in addition, $a_{11} = a_{22} \ldots a_{nn} = 0$, it is called *gauche* and *skew-symmetric*. Every such determinant of even order is the square of an integral function of its elements, which function is called a Pfaffian, it having first been discussed by Pfaff. His chief mathematical works are: *Commentatio de Orbibus et Occasibus Siderum apud Auctores Classicos Commemoratis* (1786); *Versuch einer neuen Summationsmethode* (1788); *Disquisitiones Analyticæ* (1797); *Methodus Generalis Æquationes Differentiarum Particularum Completi Integrandi* (Proceedings of the Berlin Academy, 1814-1815). His correspondence with Duke Karl of Württemberg, Bouterwek, and others was published in Leipzig, 1853.

PFANNSCHMIDT, pfän'shmit. Karl Gottfried (1819-87). A German painter, born at Mühlhausen, Thuringia. He studied painting in Berlin under Däge and under Cornelius in Munich. In 1844 he made his first trip to Italy, where he became an ardent follower of the mediæval as opposed to the Renaissance school. Many of his pictures are church decorations, and almost all are of biblical subjects. His easel pictures include a "Charity" and a "Supper," both in the Berlin National Gallery, as are the cycles from Genesis and Daniel, and that on the Lord's Prayer. His other work includes windows in the Nicholas Church, Berlin; in the cathedral at Magdeburg, and in the Stuttgart garrison church. Pfannschmidt was long professor in the Berlin Academy.

PFAU, pfou. Ludwig (1821-94). A German lyrist and art critic, born in Heilbronn. He studied in the universities of Tübingen and Heidelberg, edited the satirical *Eulenspiegel*, and took a prominent part in the revolt of Baden in 1848.

On the occasion of the revolt, Pfau was sentenced to twenty-two years' imprisonment, but he escaped to Switzerland, and after spending two years in Zurich and in Bern, settled in Paris. In 1863 he returned to Stuttgart and became editor of the *Beobachter*. His poetry is especially valuable for its political satire; *Gedichte* (1846; 4th ed. 1880) and *Deutsche Sonette auf das Jahr 1850* (1849) are the most important titles. Pfau translated many French novels, and with Hartmann a volume of Breton folk-songs (1859). But his original literary work was in art criticism as author of *Freie Studien* (1866), *Kunst und Gewerbestudien* (1877), and *Kunst und Kritik* (1888).

PFEFFEL, pfĕf'fĕl, Gottlieb Konrad (1736-1809). A German fabulist. He was born at Kolmar, and studied at Halle, where he could not finish his course because of threatening blindness. At twenty-two he lost his sight entirely. In 1773, with the help of his wife and the patronage of Louis XV., he founded a school for Protestants which enjoyed great success down to the Revolution. Pfeffel was employed in the council which undertook the reformation of the French educational system. His *Fabeln* (1783) follow Gellert for the most part; his complete works, including several very popular poems, were published at Tübingen (1810-12). Consult his biography by Lina Beck Bernard (Lausanne, 1866), and Stöber, *Pfeffels Verdienste um Erziehung und Schule* (Strassburg, 1878).

PFEFFER, pfĕf'fĕr, Wilhelm (1845—). A German botanist. He was born near Cassel, studied at Göttingen, Marburg, Würzburg, and Berlin, and became professor of botany at Bonn (1873), at Basel (1877), at Tübingen (1878), and in Leipzig (1887). His earlier botanical research was on the geographical distribution of the large-leaved mosses; afterwards he devoted himself to physiological botany. Pfeffer wrote: *Pflanzengeographische Studien aus den Rätischen Alpen* (1869); *Pflanzenphysiologie* (1882, 1897); *Ueber chemotaktische Bewegungen von Bakterien* (1888); *Beiträge zur Kenntnis der Oxydationsvorgänge in lebenden Zellen* (1889); *Physiologie und Pflanzenbau* (1890); *Energetik der Pflanzen* (1892); and contributions to the *Jahrbuch für wissenschaftliche Botanik* (1894 sqq.).

PFEFFERS, pfĕf'fĕrs. A village in Switzerland. See Pfäfers.

PFEIFFER, pfīf'fĕr, Franz (1815-68). A Germanic scholar. He was born at Bettlach, Switzerland, studied at Munich, became royal librarian at Stuttgart in 1846, and in 1857 was made professor of German literature in the University of Vienna. He was one of the most important Germanists of recent times. He founded the review *Germania*, and the series *Deutsche Klassiker des Mittelalters*, for which he edited *Walther von der Vogelweide* (6th ed. 1880). His more valuable works are: *Der Dichter des Nibelungenlieds* (1862), *Freie Forschung* (1867), and, among many editions, *Barlaam und Josaphat* (1843), *Die deutschen Mystiker des 14. Jahrhunderts* (1845-47), and an edition of the *Deutsche Ordenschronik* of Jeroschin (1854).

PFEIFFER, Ida (1797-1858). An Austrian traveler. She was born at Vienna, and began her career as a traveler by a trip to Palestine and Egypt when she was forty-five years old. This expedition was succeeded by others to Scandinavia and Iceland in 1845, and in 1846-48 to Brazil, Chile, China, India, Persia, Armenia, and the Caucasus. Another journey was taken, in 1851-55, to Africa, Australia, and America, resulting in some valuable acquisitions for the Museum of Natural History at Vienna. In 1856 she set out for Madagascar, where she was imprisoned. Broken in health, she returned thence to die. Her works, which have been translated into English, include *Journey of a Viennese to the Holy Land* (1843); *Journey to the Scandinavian North* (1846); and *A Woman's Journey Round the World* (1850).

PFEIL, pfīl, Joachim Friedrich, Count (1857—). A German explorer and colonist in Africa and New Guinea. He was born at Neurode, in Silesia, studied at the gymnasium of Göttingen, and in 1873 went to Natal. He learned the vernacular and stayed in the country four years; then (1879), after a visit to Europe, he settled in Orange Free State and with Wilson mapped the course of the Limpopo; but illness forced him to return to Germany. In 1884, having entered the employ of the Society for German Colonization, Pfeil went to East Africa with Peters and Jühlke, and in 1886 succeeded the latter as general manager of the company in Somaliland. This post he resigned in 1887, and entered the service of the New Guinea Company. His travels and explorations in the South Seas are described in his *Studien und Beobachtungen in der Südsee* (1899), and he also wrote *Vorschläge zur praktischen Kolonisation in Ostafrika* (1887), and *Zur Frage der Deportation nach den deutschen Kolonien* (1897).

PFEUFER, pfoi'fĕr, Karl von (1806-69). A German physician who introduced the rational method of physical and chemical explanations for physiological or pathological conditions. He was born at Bamberg, and studied medicine at Erlangen and Würzburg. After eight years of practice in Munich, Pfeufer held academic positions in Zurich (1840-44), in Heidelberg (1844-52), and in Munich (1852-69). Besides his great contributions to method, which appeared in the *Zeitschrift für rationelle Medizin* (1844 sqq.), he wrote on cholera, *Zum Schutz wider die Cholera* (1849; 3d ed. 1854), and introduced public sanitation as a requisite in medical study. Consult Kerschensteiner, *Leben und Wirken des Dr. Karl von Pfeufer* (Augsburg, 1871).

PFISTER, pfis'tĕr, Albrecht (*c.*1420-*c.*1470). A German printer, to whom the discovery of the art is sometimes wrongly attributed. It seems probable that he worked as wood engraver for Gutenberg. About 1455 he founded a press in Bamberg. There he printed Boner's *Edelstein* (1461); the *Book of the Four Histories* (Joseph, Daniel, Esther, and Ruth) (*c.*1462); the famous *Biblia Pauperum* (1462); and *Belial* of the same date. Consult: Hellels, *Gutenberg: Was He the Inventor of Printing?* (London, 1882), and Dziatzko, *Gutenberg's früheste Druckerpraxis* (Berlin, 1890).

PFIZER, pfit'sĕr, Gustav (1807-90). A German lyrist and critic of the Swabian school. He was born in Stuttgart, studied at Tübingen, and in 1846 became professor at the gymnasium in his native city. He wrote *Gedichte* (1831), *Dichtungen epischer und episch-lyrischer Gattung* (1840),

and *Der Welsche und der Deutsche* (1844); translations of Bulwer and Byron; the critical work *Uhland und Rückert* (1837), and an attack on Heine which called out the *Schwabenspiegel*. His poetry is more original and reflective than most of the products of the Swabian school.

PFLEIDERER, pflī'dēr-ēr. Otto (1839—). A German Protestant theologian, born at Stetten, near Cannstatt. He studied theology at Tübingen and for some time was superintendent and professor at Jena. In 1875 he was called to the chair of systematic theology at the University of Berlin. Through his writings and his lectures, he became known as one of the most influential representatives of liberal theology. His lectures in London (1885) and in Edinburgh (1894) were afterwards published in English: *Lectures on the Influence of the Apostle Paul on the Development of Christianity* and *The Philosophy and Development of Religion* (1894). His principal works are: *Die Religion, ihr Wesen und ihre Geschichte* (1869-78); *Religionsphilosophie auf geschichtlicher Grundlage* (1878-93); *Zur religiösen Verständigung* (lectures, 1879); and *Geschichte der Religionsphilosophie von Spinoza bis auf die Gegenwart* (1893).

PFLÜGER, pflü'gēr. Eduard Friedrich Wilhelm (1829—). A German physiologist, born at Hanau. He studied at Marburg and Berlin, and in 1859 became director of the Physiological Institute and professor in the University of Bonn. Pflüger made special studies on the nervous systems of lower animals; founded in 1868 the *Archiv für die gesamte Physiologie;* and wrote *Sensorische Funktionen des Rückenmarks der Wirbeltiere* (1853), *Physiologie des Elektrotonus* (1859), *Untersuchungen aus dem physiologischen Laboratorium zu Bonn* (1865), and *Ueber die Kunst der Verlängerung des Lebens* (1890).

PFLUGK-HARTTUNG, pflōōk'-härt'tung, Julius von (1848—). A German historian, best known as an authority on Papal and mediæval history. He was born at Warnikow, studied at Bonn, Berlin, and Göttingen, and in 1886 became professor of history at Basel. Thence he went to Berlin, where in 1893 he became head of the Secret State Archives. He wrote *Studien zur Geschichte Konrads II.* (1876-77); *Norwegen und die deutschen Seestädte* (1887); *Acta Pontificorum Romanorum Inedita, 748-1198* (1879-88); *Iter Italicum* (1883); in Grote's *Allgemeine Weltgeschichte* the part on the early Middle Ages (1889); *Krieg und Sieg, 1870-71*, the first of his studies of modern history (1895); *Napoleon I., Republik und Kaisertum* (1900); and *Die Bullen der Päpste bis zum Ende des 12. Jahrhunderts* (1901).

PFORZHEIM, pfôrts'hīm. A town of Baden, Germany, on the northern border of the Black Forest, 16 miles southeast of Karlsruhe (Map: Germany, C 4). It has the remains of an ancient castle, formerly the residence of the margraves of Baden-Durlach, several churches, a convent, and industrial and other schools. The Schlosskirche is a notable old structure in the Gothic and Renaissance styles. Pforzheim is one of the largest manufacturing centres of cheap jewelry in the world, over 10,000 workmen being employed. There are also chemical and iron works, machine shops, tanneries, and paper, electrical apparatus, and other factories. Population, in 1895, 33,331; in 1900, 43,097.

PFUHL, pfōōl, Johannes (1846—). A German sculptor, born in Löwenberg, Silesia. He studied in the Berlin Academy of Fine Arts under Schievelbein, became his master's assistant and completed his plans for the bronze memorial now in the Dönhoffsplatz, Berlin. Soon after Schievelbein's death Pfuhl settled in Charlottenburg. He made a few portrait busts, but his more typical products are colossal groups or reliefs, including a frieze in rilievo, commemorating the Franco-Prussian War, for the military school of Lichterfelde (1876); a statue of Count Stolberg, in Landeshut, Silesia; "Perseus Liberating Andromeda," a fountain decoration in Posen, and also in the Goethe Theatre in Charlottenburg (1884); "Theseus, Hippodameia, and Eurytion" (1886); an equestrian statue of William I. with Bismarck and Von Moltke, in Görlitz (1893); and the Laube monument at Sprottau (1895).

PHA'COPS (Neo-Lat., from Gk. *φακός, phakos*, lentil — *ὤψ, ōps*, eye, face). A genus of trilobites that furnishes several index fossils for the middle Paleozoic formations. The carapace is of oblong or elliptical form and is quite convex, with a pronounced axis, and 11 thoracic segments. The head is semicircular, with its central portion or glabella large and very wide in front. The eyes are large and conspicuous, and the lateral slopes of the head are steep, with their posterior corners rounded. The pygidium or tail piece is large, convex, and strongly ribbed. The genus Phacops ranges from Silurian to Upper Devonian formations. The early European authors generally include under this generic term a number of species that are now classed under the genera Dalmanites, Pterygometopus, Acaste, and others. The most important species are *Phacops logani* of the American Lower Helderberg, *Phacops latifrons* of the European Devonian, and *Phacops rana*, a well-known species of the American Devonian. See Trilobita.

PHÆA'CIA (Lat., from Gk. Φαιακία, *Phaiakiē*). The country of the Phæacians, a people whom Odysseus visited in his wanderings. It was situated on the mythical island of Scheria, identified with Corcyra (Corfu), where the people had settled after having been driven out of their earlier home in Hyperia by the Cyclopes. There they led an undisturbed life of happiness, occupied with their marvelous ships, which safely traversed the sea without human guidance. Odysseus was found on the shore of the island by the Princess Nausicaa, and hospitably received at the palace of her father, King Alcinous. The episode is described in the sixth, seventh, and eighth books of the *Odyssey*.

PHÆ'DO (Lat., from Gk. Φαίδων, *Phaidōn*) (early fourth century B.C.). A Greek philosopher, born in Elis. He was taken prisoner and brought to Athens, apparently about 400 B.C.; there he became acquainted with Socrates, who secured his ransom by one of his friends. He remained a devoted disciple of the great teacher until the latter's death, when he returned to Elis and became the founder of the Elean School (q.v.). He composed dialogues, no longer extant, in the Socratic manner. Plato's dialogue which describes the death of Socrates bears Phædo's name.

PHÆ'DRA (Lat., from Gk. Φαίδρα, *Phaidra*). In Greek legend, the daughter of Minos, King of

Crete, and of Pasiphaë, sister of Ariadne and wife of Theseus. Aphrodite, enraged against Hippolytus (q.v.), Phædra's stepson, for neglecting her worship, and against Phædra, as being the daughter of Pasiphaë, inspired the latter with a passion for Hippolytus. On the rejection of her advances, she falsely accused the youth to Theseus, who prayed to his father, Poseidon, to destroy his son. Hippolytus was thrown from his chariot on the seashore and dragged upon the sands till dead. Phædra died by her own hand and Theseus learned the truth too late. This story, which seems to have been developed from the songs of Trœzenian maidens to their local divinity, Hippolytus, guardian of purity, was first treated in tragedy by Euripides, whose second version has been preserved. It was also treated in a lost play by Sophocles. The Greek tragedy was imitated by the Roman Seneca, and also by Racine, whose *Phèdre* (1677) is one of his masterpieces. Consult Euripides, *Hippolytos*, ed. U. von Wilamowitz-Moellendorff (Berlin, 1891).

PHÆ'DRUS. A Latin fabulist. He was probably a Thracian, who was carried to Rome as a slave in his childhood, and brought up at the Court of Augustus, who emancipated him. Under Tiberius he was exposed to great danger from the hostility of Sejanus, but lived to see that favorite's overthrow, and died at an advanced age, probably in the reign of Claudius. Five books of fables, after the manner of Æsop, and called *Fabulæ Æsopiæ*, have been ascribed to him. Most of the fables are versifications of those of the Æsopian cycle, but many are drawn from contemporary story. The style is good, and the metre is careful. The book, as we have it, is a later and incomplete recension. The first edition was published at Troyes in 1596. The best later editions are those of Müller (Leipzig, 1877, with critical notes), Ramavino (Turin, 1881), and Müller (Leipzig, 1890). See Hervieux, *Les fabulistes latins* (Paris, 1893-96); Bédier, *Les fabliaux* (Paris, 1893). See Æsop.

PHÆDRUS. A dialogue of Plato, in which he is represented walking in the woods with Phædrus, and discoursing on the nature of love. The dialogue is distinguished by unusual poetic enthusiasm. The latter portion is an exposition of dialectics.

PHÆOPHY'CEÆ (Neo-Lat. nom. pl., from Gk. *phaiós*, *phaios*, dusky = *phôkos*, *phykos*, seaweed), or BROWN ALGÆ. A group of algæ named from the color of the chromoplast, always a shade of brown, a color due to the pigment phycophæin, which modifies or overpowers the green of the chlorophyll. In some respects the most remarkable of the four great groups of algæ, comprising the largest and most vegetatively complex forms.

The Phæophyceæ are characteristically inhabitants of the colder waters of the globe, and are almost all marine, reaching their maximum development in Arctic and Antarctic oceans, and along such coasts as the Californian seaboard, where the water for the most part is cold. The display is especially luxuriant at Cape Horn, and on the rocky coasts of the North Atlantic and Pacific oceans. The brown algæ contain a large number of diverse groups, whose representatives range from microscopic forms and delicate filamentous types (Ectocarpales) to the immense coarse kelps several hundred feet long. The Laminariales (kelps, devil's aprons) generally have a stalk (stipe) attached to the rocks by a cluster of strong root-like processes (holdfast), that ends in an expansion called the blade, which in some forms bears lateral leaf-like structures. The blade is simple in the smaller forms (Laminaria), or perhaps split up longitudinally into segments. In many types the blade is cast off at certain periods by the development of a new one through the activity of the tissues just below the old. In other genera the blade serves as the growing region of the plant, and splits off segments which take a lateral position on the stem (Macrocystis).

The most interesting forms on the American coast are the giant kelps of the Pacific Ocean. Macrocystis is reported to attain a length of 900 feet. It is easily recognized by the leaves borne on a stem about the size of a clothes line. Far

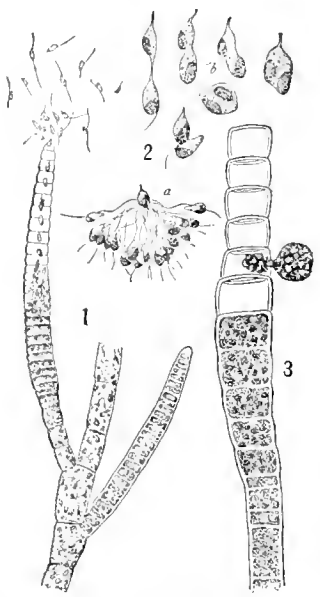

FIG. 1. BROWN ALGÆ.

1, Ectocarpus, with gametes escaping; 2, conjugation of the same, showing (*a*) numerous male gametes about a single female gamete, and (*b*) various stages of fusion; 3, Pylaiella, with one cell functioning as a sporangium.

more picturesque is the sea-otter's cabbage (Nereocystis), which consists of a flexible leafless stalk swollen at the end into a hollow spherical float several inches in diameter. The top of the float bears long strap-like leaves that extend on either side in the water, and are whipped about by the wind and surf. Another interesting form is the sea-palm (Postelsia), which grows on surf-beaten rocks and reefs, and has a heavy, thick, erect stalk 12 to 18 inches high, with a thick crown of leaves that grow out and bend downward in the form of the conventional palm tree. The stalk is so tough that it may be bent over at right angles by the force of the waves without breaking. Lessonia, found on the coast of Chile, has stalks so heavy and thick that they have been mistaken for tree trunks when washed up on the beach. The kelps are one of the principal sources of iodine, which

is obtained from their ashes. They are also used in enriching farm lands along the coast.

In a very different division of the Phæophyceæ

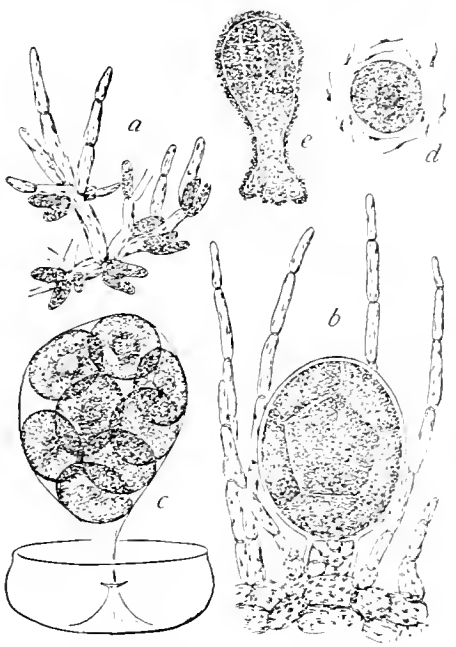

FIG. 2. ROCKWEED (*Fucus*).

a, branches bearing antheridia; *b*, oögonium with paraphyses; *c*, eggs escaping from oögonium; *d*, egg surrounded by sperms; *e*, germination of a fertilized egg.

are the 'rockweeds' and 'gulfweeds.' The former, also called 'wrack' and 'bladder-wrack,' cover the rocks between tide marks with thick fringing growth. Most of the rockweed is Fucus, a form with a forkingly branched thallus, that bears swollen tips, and in some species special air bladders that serve to float the branches. The gulfweeds (Sargassum) have one of the most highly differentiated vegetative bodies among the algæ. The species are found in warmer waters than most brown algæ. In addition to the holdfast and branching stalk, there are delicate leaves and small berry-like air bladders on short pedicels, besides specialized portions that bear sexual organs. Certain species (as Sargassum bacciferum) will vegetate luxuriantly when floating in mideocean, thus forming the large masses of gulfweed met by ships, especially in certain warmer parts of the Atlantic.

Reproduction among Phæophyceæ is either sexual or non-sexual. In non-sexual reproduction motile spores (zoöspores) are formed by the division of the protoplasm of a cell and the escape of the organized parts into the water (Fig. 1, 3). Sexual reproduction is either isogamous or heterogamous. In isogamous union sex cells (gametes), in form and origin like zoöspores, fuse in pairs. Sometimes in behavior they can be distinguished as male and female, as in Ectocarpus (Fig. 1, 2, *a*, *b*). Heterogamous reproduction may be illustrated by Fucus. The eggs, eight in number (Fig. 2, *b*), are formed in a specialized oögonium, which develops in a pit on the surface of a swollen branch, called a conceptacle. They escape into the water, where they are met by biciliate sperms (*d*) which have been produced in numbers in special cells of the branched hairs arising in similar pits. Fertilization occurs by the union of sperm and egg. The latter then grows at once into a new rockweed, its base developing into a holdfast and its apex into a thallus (*e*).

The most comprehensive treatment of the group is in Engler and Prantl, *Die natürlichen Pflanzenfamilien* (Leipzig, 1887—); Murray, *Introduction to the Study of Seaweeds* (New York and London, 1895). See ALGÆ.

PHAER, fā'ẽr, or **PHAYER**, THOMAS (1510?-1560). An English translator, educated at Oxford and at Lincoln's Inn. As a lawyer he aimed to popularize legal methods. To this end he wrote two legal handbooks. Rewarded for his service by the appointment as solicitor in the court of the Welsh marches, he settled at Kilgerran, in Pembrokeshire, where he passed most of his life. He also studied medicine, and published a popular book called *The Regiment of Life*, containing a treatise on the plague (1546). To the *Mirror of Magistrates* (1559) he contributed a poem on a legend connected with Owen Glendower. Phaer is now remembered chiefly for his translation of Vergil's *Æneid* into English ballad metre (7 books, 1555-58; two more books, published posthumously with the first seven, 1562). The translation was completed by Thomas Twine in 1584. Vergil had been translated earlier into the Scotch dialect by Gawin Douglas (q.v.), and the Earl of Surrey (q.v.) had completed two books.

PHA'ËTHON (Lat., from Gk. *φαέθων*, shining). In the Greek poets, a not infrequent title of Helios, the sun-god. Phaëthon, in Greek legend, is also a son of Helios and the Oceanid Clymene. To prove his descent, he went to his father's palace and insisted on attempting to drive the chariot of the sun. Unable to control the fiery horses, he was carried from his course, and, approaching too near the earth, wrought great damage. Whereupon the earth cried to Zeus for help, who struck down Phaëthon with a thunderbolt into the Eridanus, a mythical river, later identified with the Po. His sisters, the Heliades, found the body, and bewailed the loss until they were changed to poplars and their tears to amber, to which the rays of the sun gave its special glow. In the lost *Phaethon* of Euripides the youth appeared as the favorite of Aphrodite, who had placed him in charge of her temple. Consult Knaack, *Quæstiones Phaethonteæ* (Berlin, 1885).

PHAETON. A form of carriage for pleasure-driving drawn by one or two horses. The term is more often applied to a low easy carriage driven by ladies and known as a pony phaeton, although there are the mail phaeton and the spider phaeton, which are high carriages suitable for park driving, with a seat in front for the driver and a companion, and a rear seat for a groom.

PHAËTON. See TROPIC-BIRD.

PHAGEDENA, fāj'ẽ-dẽ'nà (ML., from Lat. *phagedæna*, from Gk. *φαγέδαινα*, *phagedaina*, cancer, from *φαγεῖν*, *phagein*, to eat). A term used in surgery to designate any obstinate and rapidly destructive form of ulceration. The process usually occurs in those whose systems are exhausted by disease and whose vitality is lowered by un-

hygienic surroundings. When an ulcer assumes a phagedenic character it enlarges rapidly: its edges are ragged and thin: its base is covered with an unhealthy slough: the discharge is thin, reddish, and offensive, and around the whole is a zone of red and deeply congested tissue. There is no tendency toward healing. The treatment consists in the local application of caustics or excision, and the administration of stimulants, tonics, and nutritious food, together with measures to promote the most favorable hygienic conditions.

Phagedena gangrænosa is a term sometimes applied to 'hospital gangrene,' a disease which formerly prevailed in prisons and hospitals, but which, owing to sanitary reform and the introduction of antiseptic measures, is now practically extinct.

PHAGOCYTE (from Gk. *φαγεῖν*, *phagein*, to eat + *κύτος*, *kytos*, hollow, cell). A microbe-destroying cell residing free in the animal system. About 1883 Metchnikoff found that the individual cells of the stomachs of sponges took in solid particles of food and digested them, and this he called intracellular digestion. This function is performed by individual, free, or 'wandering' mesoderm cells, resembling amœbæ. Such wandering cells, in the cases of many of the lower animals, ingest or absorb parts of the body which become useless or by decay harmful to the organism. Besides this these free amœboid cells can and do capture and devour foreign bodies and particles; they take up anything hard or soft which occurs in or is carried into the body; and when such cells are confronted with a large mass of food-material, which they cannot devour singly, they usually fuse into a plasmodium, which eats up the whole available food. Such bodies as cannot be eaten are surrounded and isolated. Led by these facts, Metchnikoff threw out the remarkable theory that inflammation in the vertebrates is due to the struggle between the white corpuscles of the blood and the disease-germs within it. Thus a new importance was lent to the leucocytes or white amœboid corpuscles, viz. that they act as microbe-eaters or 'phagocytes.' Metchnikoff injected fluids containing bacteria or microbes beneath the skin of various invertebrate animals. They were soon found within the amœboid cells, and if such microbes developed spontaneously in the wounds of such animals, they were absorbed in the same manner. Kovalevsky, a few years later, made similar observations in compound ascidians. When an individual died it was attacked and absorbed by the mantle cells of the colony, which also sought to destroy incoming bacteria, as was proved by experiment. Kovalevsky concluded that the passage of the wandering cells to the surface of the epithelium is a means of protection against the intrusion of agents of disease. These discoveries and theories mark an epoch in biology in its application to medical knowledge.

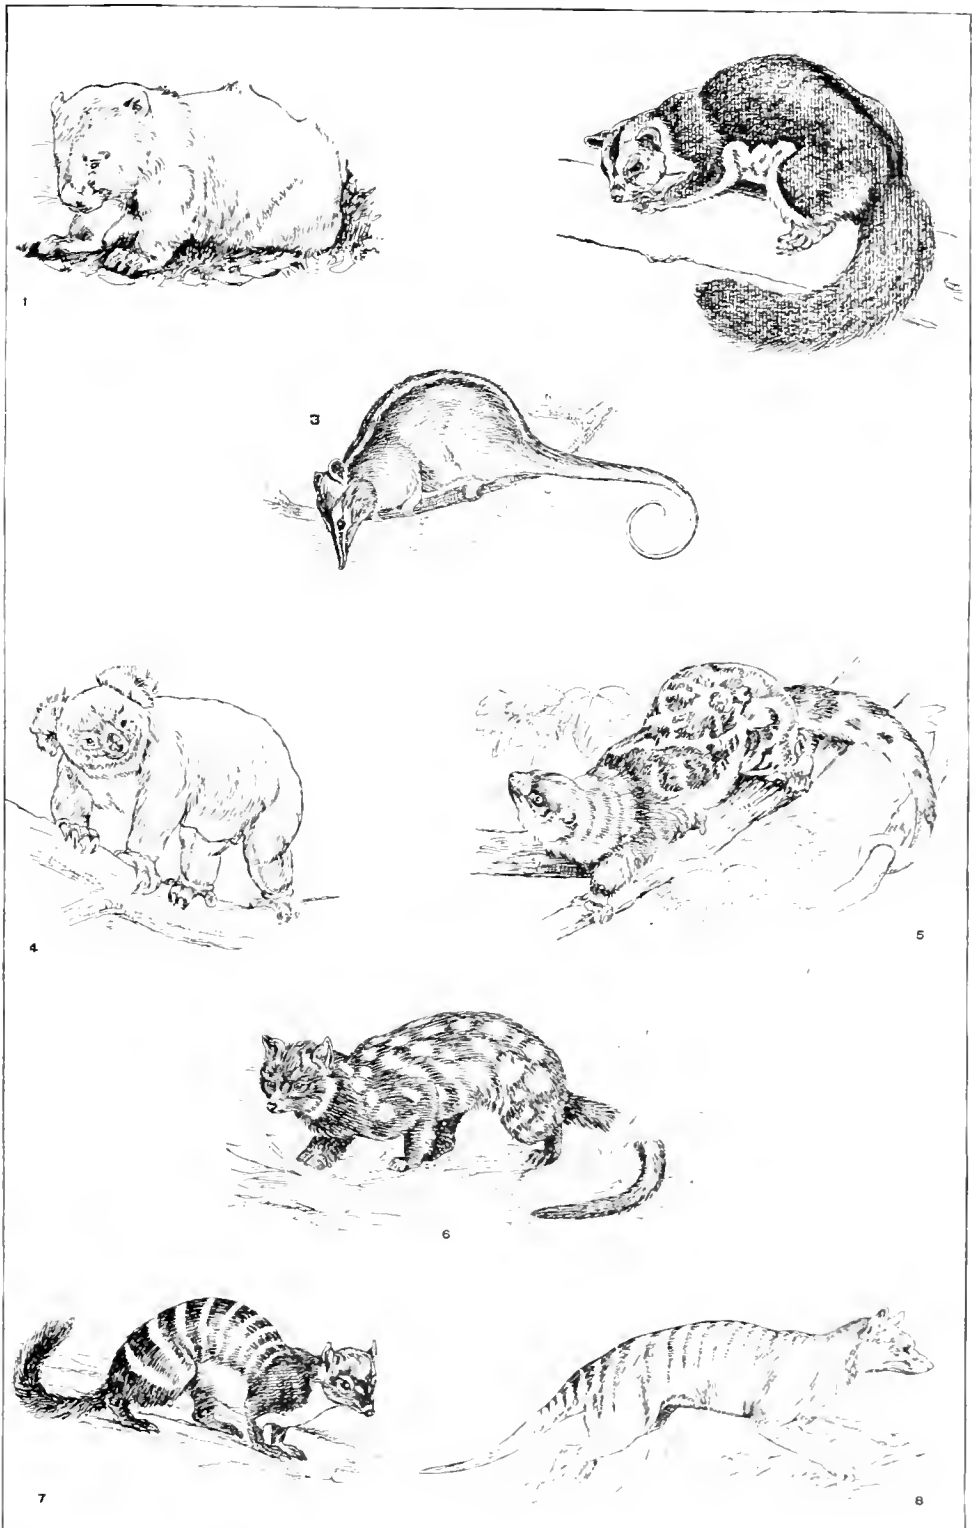
PHAG'OCYTO'SIS. See INFLAMMATION.

PHALANGER (Fr. *phalanger*, from *phalange*, phalanx, from Lat. *phalanx*, from Gk. *φάλαγξ*, line of battle, rank of soldiers, round piece of wood, joint between the fingers and toes). Any of the marsupials of the family Phalangeridæ, which are characterized preëminently by having five fingers and toes, the second and third bound together. The thumb is opposable and nailless. The tail is nearly always long and prehensile. The family is divisible into four sections, and includes a considerable variety of form. Thus the true or typical phalangers include the various species of cuscus (q.v.), and various largish species, some arboreal and some terrestrial, besides the petaurists or flying phalangers (q.v.; also TAGUAN), and the 'dormouse phalangers' of the genus Dromicia. Another group contains the koala (q.v.), a third the wombat (q.v.), a fourth the aberrant little tarsipes of Western Australia, which is only seven inches long, and uses its long, slender tongue to extract honey from flowers, as well as to catch the small insects which constitute most of its food. The phalangers are united with the kangaroos by descent, and are now separated from them only by the musk-kangaroo (Hypsiprymnodon). Typical members of this family are shown in the accompanying plate.

PHALANX (Lat. *phalanx*, from Gk. *φάλαγξ*, line of battle, row of soldiers, round piece of wood, joint between the fingers and toes). The ancient Greek name for the heavy infantry in line of battle. The heavy-armed hoplites were only of service when stationed in a long straight line in close order. In the Homeric poems there are only shadowy traces of a regular line of battle, and the development of the typical Greek formation seems to have been largely the work of the Spartans during their struggles for supremacy in the Peloponnesus. As the principle of formation was the desire to present an equal line to the enemy, the depth and formation depended on circumstances. The usual depth seems to have been eight men, but Miltiades at Marathon weakened his centre in order to extend his line, and at Delium the Theban column was twenty-five deep. It is not until the fourth century B.C. that we find other troops of practical importance in deciding the Greek battles. During that century the improved equipment of the *peltasts*, or light-armed troops, made them able to meet the phalanx, if able to choose their ground and avoid the direct attack. Epaminondas gave a new direction to the art of war by replacing the old attack along the whole line with the decisive onset of one wing, drawn up in a heavy column (at Leuctra fifty deep), while the rest of the line in ordinary depth served to check the enemy. Philip of Macedon learned his military science at Thebes, and reorganized his army by the introduction of a regular infantry besides the hereditary cavalry of the nobles. These soldiers were armed with a small shield, about eighteen inches in diameter, corslets, and long spears, and fought in closer order than was usual among the Greeks. This phalanx seems to have been a mobile body, but probably Philip and certainly Alexander relied rather on the heavy cavalry as the offensive force, and used the phalanx to hold the main line of the enemy in check, while the cavalry crushed his wing or turned his flank. The phalanx of



1. WOMBAT (Phascolomys Mitchelli).
2. FLYING SQUIRREL PHALANGER (Petaurus sciureus).
3. LONG-SNOUTED PHALANGER (Tarsipes rostratus).
4. KOALA (Phascolarctos cinereus).
5. CUSCUS (Phalanger maculatus).
6. COMMON DASYURE (Dasyurus viverrinus).
7. BANDED ANT-EATER (Myrmecobius fasciatus).
8. TASMANIAN WOLF (Thylacinus cynocephalus).

Alexander seems to have had pikes of different lengths, the longest being about seventeen feet, and of course requiring the use of both hands. Though intended to fight in line as a single mass, it was also capable of breaking into small tactical units able to manœuvre separately, if the nature of the ground or the development of the battle made it desirable. The successors of Alexander gradually changed his fundamental principles, and depended again upon the phalanx to decide the day. This led to even closer massing of men and increase of the length of the lances, till the mass became irresistible if unbroken, but unwieldy and utterly helpless if broken by uneven ground, as was proved in many a battle against the Roman legions. This later phalanx was regularly drawn up sixteen men deep, and either about three feet apart, body included, or only about eighteen inches with shields touching; a formation which made any turning on the part of individuals impossible. The lances were about twenty feet long, and those of the first five ranks projected in front; the others held their spears over the shoulders of their comrades, ready to drop them if occasion arose. Consult: Droysen, "Griechische Kriegsalterthümer," in Hermann, *Lehrbuch der griechischen Antiquitäten* (Freiburg, 1888); Bauer, in Müller's *Handbuch der klassischen Altertumswissenschaft*, vol. iv. (Munich, 1893); Delbrück, *Geschichte der Kriegskunst* (Berlin, 1900); Lammert, *Polybios und die römische Taktik* (Leipzig, 1889).

PHAL'ARIS (Lat., from Gk. *Φάλαρις*). A tyrant of Agrigentum in Sicily, whose rule lasted from about 570 to 549 B.C., when he was killed in a popular revolt. He maintained himself by mercenaries, and chiefly by stratagem extended his power on all sides. The tradition, at least as old as Pindar, that he gratified his savage nature by roasting persons alive in a brazen bull, has made him the universal type of the cruel tyrant. A collection of letters which bears his name represents him as a kindly and cultivated prince; but Bentley in his famous *Dissertation* (first published in 1699) showed that these are probably forgeries of the Christian Era. See BENTLEY, RICHARD. Consult: Freeman, *History of Sicily*, (Oxford, 1891).

PHALARIS. See CANARY-GRASS.

PHAL'AROPE (from Gk. *φαλαρίς*, *phalaris*, coot, *πούς*, *pous*, foot). A sandpiper-like shorebird of the family Phalaropodidæ, having lobate feet and a rather long bill, which is slender, weak, and straight. Phalaropes differ from sandpipers, however, in that they spend the greater part of their time in swimming on the sea, where they seek mollusks and other small marine animals for their food. They are very fearless of man and are said to be easily tamable, but the flesh is oily and unpalatable. The phalaropes differ from most other birds in the remarkable relative condition of the two sexes. The females are not only larger and more brightly colored, but they do the courting, and, after they have secured a mate and laid their 3 or 4 eggs, they leave the male to do the incubating. Three species only are known, all inhabitants of the Northern Hemisphere and two circumpolar. Each is now made the type of its own genus. The northern phalarope (*Phalaropus lobatus*) has the membrane of the toes scalloped and the bill very slender. It breeds in the Arctic regions and migrates southward on the approach of winter. The nest is a shallow depression in the ground lined with grass and moss. The eggs are olive-gray or buffy-white, heavily blotched with chocolate-brown. Its entire length is rather less than 8 inches. The tail is short. It is a beautiful bird, and remarkable for the great difference of its summer and winter plumage, the prevailing tint in winter being a delicate gray, while in summer the upper parts exhibit a fine mixture of slate-gray and buff, sides and front of neck rufous, and the breast and under parts are white. The red phalarope (*Crymophilus fulicarius*) is rather larger than the northern phalarope, and is, like it, very graceful in form and movements, and finely colored. The membrane of the toes is scalloped, but the bill is stouter, flattened, and has a lancet-shaped tip. The third species is Wilson's phalarope (*Steganopus tricolor*), which is an American bird, found in summer north to the Saskatchewan, and in winter south to Brazil and Patagonia. It is rare in the East, but abundant in the Mississippi Valley. It is the largest of the three species, being nine inches or more in length. The toe-membranes are plain and unscalloped. Consult: Coues, *Birds of the Northwest* (Washington, 1874). See Plate of EGGS OF WATER AND GAME BIRDS.

PHALLICISM, or PHALLISM (from *phallic*, from Gk. *φαλλικός*, *phallikos*, relating to the male organ, from *φάλλος*, *phallos*, male organ). The worship of the generative power, as expressed most strongly by adoration of the male organ. As a cult, phallicism is typical of the Oriental races, especially Semitic and Dravidian. In Europe its strongest expression is found in Greece, which was under Semitic influence; but as a phase of other worship, rather than as a special cult, it is native to many savage tribes of America and Asia. Under a corresponding name, linga-worship, phallicism is still practiced by the natives of India. There are two forms of phallicism. The lower, and probably earlier, form is found when the phallos itself is worshiped as divine or is regarded as emblematic of sexual passion alone. Ordinarily, in this form, the phallic emblem is the mark of devotion to some deity of lust, who is not necessarily a male divinity. On the contrary, the female deity is more usual and sometimes older than the male. In the latter case we have reverence paid to the divine mothers, or female forms, of India; to the date-palm, mother-goddess in Arabia, etc.; in the former we find the worship of Dionysus in Greece and Siva in India. In this first form of phallicism there is no notion, or only a very vague notion, of affinity between sexual instinct and the creative power of nature. Among savages the rite in this form is scarcely more than a frankly brutal indulgence of passion; in a civilized community, where excess is frowned upon by a more refined sentiment, the indulgence tends to become secret, as in the Tantric worship of India. This Hindu phallicism, with its conventional admixture of philosophy, represents the conditions which obtained in Greece when orgies were veiled as Orphic mysteries.

In the second form the phallos serves merely as a symbol of that mysterious force which in spring renews vegetable life and awakens to fresh energy all living things, and phallicism thus refined becomes the worship of a great divine uni-

fy ... and creative power. Such phallicism as this ... the religion of ascetics, like the Lingaites of India, and in this case the phallic emblem is usually two-fold, as the deity is regarded as androgynous. But the two emblems, no longer realistic, are merely conventionalized shapes, which are placed in the temples of the male-female god Siva. Such was probably the phallicism of the higher minds in Greece, and to them the Orphic mysteries were a philosophical reinterpretation of the naive form of grossly material phallicism which alone appealed to the vulgar.

Phallicism is not necessarily primitive, although found in very savage communities. Among the Central Australians, for example, there are erotic dances, but no trace of phallic worship. Finally it is to be observed that many supposed phallic survivals, such as the *swastikas* (q.v.) and upright stones, may have in reality nothing to do with phallic worship. Phallicism, however, lies at the base of various savage rites in many parts of the world, Asia, Africa, and America, and was often connected, as among the Aztecs, with higher forms of nature-worship. Consult: Tylor, *Primitive Culture* (Boston, 1874); Fergusson, *Rude Stone Monuments* (London, 1872); Barton, *Semitic Origins* (New York, 1901).

PHANARIOTS. See FANARIOTS.

PHAN'EROGAM (from Gk. *φανερός, phaneros*, evident + *γάμος, gamos*, marriage). An old name of spermatophytes (q.v.), popularly called flowering plant. They are also called 'phenogams' or 'phenogans.' See CRYPTOGAMS.

PHAN'EROGLOS'SA (Neo-Lat., from Gk. *φανερός, phaneros*, evident + *γλῶσσα, glōssa*, tongue). A suborder of the Anura (q.v.), containing those frogs and toads which possess a tongue, which has the shape of a round disk adherent by nearly the whole of its base, and is not protrusible. This group includes the great majority of the frogs and toads of the world. Consult Gadow, *Amphibia and Reptiles* (London, 1901).

PHAN'OCLES (Lat., from Gk. *Φανοκλῆς, Phanoklēs*). A Greek elegiac poet of the close of the fourth century B.C. Of his life we know nothing. His poems deal with the loves of the gods for beautiful boys; the tragic vengeance in each case seems to have been particularly stressed. Apart from some merely verbal fragments, there remains of this series only one considerable piece from a poem on Orpheus's admiration for Calaïs, which shows much beauty of diction and versification. It is edited in Bergk's *Anthologia Lyrica*.

PHARAOH. *fā'rō or fā'rā-ō* (Heb. *Par'ōh*, Gk. *Φαραώ, Pharaō*). The Hebrew form of the Egyptian *Per-o*, used in the Bible as the general name or title of the kings of Egypt. From motives of reverence, the Egyptians avoided using the name of their sovereign, and usually substituted for it some such expression as 'the good god,' 'Horus the lord of the palace,' 'his Majesty,' 'the King,' or, especially under the New Empire, the indefinite pronoun 'one.' A very old designation of this nature was *Per-o*, 'great house' (i.e. the palace). It occurs as early as the Fourth Dynasty, was used with special frequency in the vernacular of the New Empire, and finally, at quite a late period, became the common popular designation of the Egyptian monarchs. It is preserved in the Coptic *perro*, 'the King,' where the *p* is mistaken for the definite article. Josephus (*Antiq.*, viii. 6, 2) correctly explains Pharaoh as meaning 'King,' and as late as the fourth century A.D. Horapollo seems to have known that 'great house' was a synonym of 'King.' Consult: Ebers, *Aegypten und die Bücher Moses* (Leipzig, 1868); Cheyne and Black, *Encyclopædia Biblica*, vol. iii. (London, 1889, et seq.).

PHARAOH'S HEN, or PHARAOH'S CHICKEN. The small Egyptian vulture (*Neophron percnopterus*), so called because of its frequent appearance in the ancient hieroglyphs.

PHARAOH'S RAT. The Egyptian mungoos (*Herpestes ichneumon*).

PHARISEES (Heb. *pĕrūshīm*, Aramaic *pĕrīshīn*, the set apart, separatists). A Jewish religious party. The Pharisees first emerged as a definite party when the success of the Maccabean revolt led to the foundation of a secular State, at the head of which John Hyrcanus (high priest, B.C. 135-105) reigned as a secular prince, making alliances with other powers. Opposition to this policy, along the line of the old spirit of separation from all things non-Jewish (see GENTILES), crystallized in the party of the Pharisees. They were essentially a religious party and used political methods only when their principles had been severely outraged or when they could not otherwise attain their ends. Their distinctive doctrines were: (1) Separation from all intercourse in common life with the mass of the people, whom they designated as the *'am hā'āreṣ* (people of the land). This term did not include, as it had originally done, the heathen inhabitants of the land, from whom Jehovah was supposed to have commanded the Israelites to keep apart for fear of contamination (cf. Ezra ix. 1; Neh. x. 28-31); it was used by the Pharisees to designate even their orthodox fellow countrymen who were less scrupulous than themselves in the interpretation and observance of the law. Since absolute separation was impossible, they drew up elaborate rules to govern their intercourse with the mass of their fellow-countrymen. They would not buy or sell in exchange with an *'am hā'āreṣ;* their great Rabbi Hillel said, "No *'am hā'āreṣ* is pious." They worshiped, however, with their countrymen in the temple and synagogue, and Hillel also said, "Separate not thyself from the congregation." Nevertheless the Pharisees stood highest in the popular favor. (2) Less distinctive, but held with equal intensity, was their doctrine of the strict interpretation and rigid observance of the law as a necessity to righteousness. They insisted upon both the written law (the Torah) and also the traditions of the elders. Indeed, they made the tradition of more weight than the law (Mark vii. 8 sqq.). One of their principles was, "It is a greater crime to teach contrary to the precepts of the scribes than contrary to the Torah itself." The law was extended by them to the minute details of the ablution of hands and vessels, to tithes, fasts, and Sabbath observance. They were the strictly legal party; righteousness was the product of legal observance, according to their teaching. (3) They cherished the political ideal of a restoration of the kingdom of Israel, which they expected to be accomplished through the interposition of a divine act; preparation for

this consummation they believed was best achieved through a strict carrying out of the law. Foreign domination they regarded as a punishment of God for the sins of the people. (4) Their other doctrines, regarding the immortality of the soul, providence, and human freedom, were less peculiar and held in common with other Jews.

The Pharisees are most familiar through their relation to Jesus of Nazareth. They became his bitter opponents early in his ministry and continued so until the end. The grounds of their hostility were many. He and his disciples mingled freely with publicans and sinners, thus violating the distinctive Pharisaic doctrine of separation from the *'am hā'āreṣ*. They were careless about the strict observance of fasts, ablutions, and the Sabbath. The teaching of Jesus concerning the Fatherhood of God was in direct opposition to the letter and spirit of Pharisaic legalism. His interpretation of the Torah in the Sermon on the Mount was a repudiation of the Pharisaic principle that righteousness is the result of the strictness with which commandments affecting the external life are observed. The Pharisees made the religious relation one of legal compact; Jesus made it one of personal fellowship in the bond of filial trust and obedience. These two systems were utterly contradictory; the representatives of the one could not endure the teacher of the other. Hence the Pharisees were the most active in putting Jesus to death. After the destruction of Jerusalem under Titus (A.D. 70) the Pharisees survived as a party; their leading rabbis formed a body which regarded itself as the continuation of the ancient Sanhedrin; this group persisted and preserved Judaism of the stricter sort after the theocracy was really overthrown.

(New York, 1900); Prince, article "Scribes and Pharisees," in *Encyclopædia Biblica*, vol. iv. (London, 1903).

PHARMACEUTICAL ASSOCIATION, AMERICAN. A scientific society with its headquarters at Baltimore, Md. Its initial meeting was held in New York in 1851. The association was organized in Philadelphia in 1852, and incorporated in Washington, D. C., in 1888. Its objects are to improve the science and art of pharmacy by diffusing scientific knowledge among apothecaries and druggists, to foster pharmaceutical literature, to stimulate discovery and invention, and to encourage home production and manufacture in the several lines of drugs. It has published annual volumes of proceedings since 1851, except for the year 1861.

PHARMACOPŒIA (Neo-Lat., from Gk. φαρμακοποια, *pharmakopoiia*, art of preparing drugs, from φαρμακοποιος, *pharmakopoios*, one who prepares drugs, from φαρμακον, *pharmakos*, drug, medicine + ποιειν, *poiein*, to make). A term applied to various works, consisting for the most part of (1) a list of the articles of the materia medica, whether simple or compound, with their characters, and the tests for the determination of their purity; and (2) a collection of approved receipts or prescriptions, together with the processes for articles in the materia medica, obtained by chemical operations. Almost every civilized country of importance has its national pharmacopœia, among which those of the United States, Great Britain, France, and Prussia deserve honorable notice. The first pharmacopœia published under authority appears to have been that of Nuremberg in the year 1542. Valerius Cordus, a student, who was staying for a short time at Nuremberg, showed a collection of medical receipts, which he had selected from the works of the most eminent writers, to the physicians of that city, who were so struck with its value that they urged him to print it for the benefit of the apothecaries, and obtained for his work the sanction of the senatus. Before this time the books chiefly in use among apothecaries were the treatises: *On Simples*, by Avicenna and Serapion; the *Liber Servitoris* of Balchasim ben Aberazerim; the *Antidotarium* of Johannes Damascenus or Mezue, arranged in classes; and the *Antidotarium* of Nicolaus de Salerno, which was arranged alphabetically. This work was commonly called *Nicolaus Magnus*, to distinguish it from an abridgment known as *Nicolaus Parvus*.

The first edition of the London pharmacopœia (or, more correctly speaking, of the pharmacopœia of the London College of Physicians) appeared in 1618, and was chiefly founded on the works of Mezue and Nicolaus de Salerno. Successive editions appeared in 1627, 1635, 1650, 1697, 1721, 1746, 1787, 1809, 1824, 1836, and 1851, and form an important contribution to the history of the progress of pharmacy and therapeutics during the last two centuries and a half.

The Edinburgh pharmacopœia is more modern than the London, the first edition having appeared in 1699, while the Dublin pharmacopœia does not date farther back than 1807. The latest editions of these works appeared in the years 1841 and 1850 respectively.

Until the Medical Act passed in 1858, the right of publishing the pharmacopœia for England, Scotland, and Ireland was vested in the colleges of physicians of London, Edinburgh, and Dublin respectively; and as these three pharmacopœias contained many important preparations, similar in name, but totally different in strength (as, for example, dilute hydrocyanic acid, solution of hydrochlorate of morphia, etc.), dangerous complications arose from a London prescription being made up in Edinburgh or Dublin, or vice versa. By that act is is ordained that "the general (medical) council shall cause to be published, under their direction, a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed; and containing such other matter and things relating thereto as the general council shall think fit, to be called *British Pharmacopœia*, which shall for all purposes be deemed to be substituted throughout *Great Britain* and *Ireland* for the several above-mentioned pharmacopœias."

The *British Pharmacopœia*, of which mention has just been made, a work published in 1864, had the merit of amalgamating the London, Edin-

[illegible] pharmacopœias; but it unfortunately contained so many defects that, in accordance with the universal wishes both of the medical profession and of the chemists, the medical council ordered a new edition to be prepared as speedily as possible. This edition appeared in 1867, and has been followed by others in 1874, 1885, and a supplement in 1890. The French pharmacopœia is used in Switzerland also. The Prussian pharmacopœia is used in Germany and Russia. The pharmacopœia of Orosi is used in Italy.

It may be proper here to make the distinction between a pharmacopœia and a dispensatory. These terms have been used indiscriminately, but there is a distinction among pharmacists. A pharmacopœia is strictly a collection of recipes or instructions for making various medicinal compounds, or simple preparations, which are also made under the authority of a college or body of medical men, and are termed 'official'. A dispensatory is a book which also treats of the preparation of medicines; but it moreover contains the natural as well as the medical history of the various medicinal substances. A dispensatory, in addition to official preparations, may contain many others, and be published without official authority. A dispensatory is also to a greater or less extent a treatise on *materia medica* (q.v.), a branch of medical science which treats of the knowledge and action of medicines, and may either treat of the action of individual medicines or embrace the whole range of the pharmacopœia, and occupy itself with the action of every article, simple or compound, either upon a healthy or a diseased subject; that is to say, it may consider the physiological as well as the therapeutic action of medicines, therapeutics (q.v.) being that branch of the science which treats of the action of drugs as *medicines* strictly speaking, or their action in disease; for this is often very different from their action on the healthy body, or their physiological action. A dispensatory is generally a combination of a pharmacopœia, a materia medica, and a treatise on therapeutics, as far as the latter is not included in materia medica.

In many of the countries of Europe the pharmacopœia is published by authority of the Government, and its requirements are enforced by law. In the United States this is not so, but in many of the individual States the "Pharmacopœia of the United States of America" has been adopted as the legal standard. In 1778 the first pharmacopœia in this country was published in Philadelphia for the use of a portion of the American army. Another was published in 1805 for use in New England. The New York Hospital issued one for its own use in 1815; later editions, like those of similar institutions, being known as the Formulary and consisting of classified collections of prescriptions. The New York County and New York Medical Societies in 1818 took measures for holding a convention of delegates from various State medical societies and medical colleges, which met at Washington January 1, 1820. The action taken then resulted in the appearance the same year of the first *Pharmacopœia* in the United States of America, a volume of 272 pages in Latin and English. Since the edition of 1840 the Latin has been [illegible]. The convention made provisions for the [illegible] other conventions for revision every te[illegible] convention of 1860 received delegates from the army and navy, and from various colleges of pharmacy and pharmaceutical societies. Following the convention held at Washington in 1890, the seventh revised edition was published in 1893. The first edition of the *United States Dispensatory* was issued in 1831. It has since that time passed through many revisions, and has become double its original size, till at the present time it is really an encyclopædia of therapeutics, pharmacy, and materia medica. Several other excellent pharmacopœias and dispensatories have been published, the *National Dispensatory* and the *American Dispensatory* being the most prominent. Though valuable, they do not occupy the official position that is filled by the pharmacopœia. New preparations are, of course, continually added to the pharmacopœias.

PHARMACY (OF. *farmacie*, Fr. *pharmacie*, from Gk. φαρμακεία, *pharmakeia*, use of drugs, from φάρμακον, *pharmakon*, drug, medicine). That department of *materia medica* (q.v.) which treats of the collection, preparation, preservation, and dispensing of medicines. It is synonymous with *pharmaceutical chemistry*.

PHAR'NABA'ZUS (Lat., from Gk. Φαρνάβαζος, from OPers. **Farnābazu*, having an arm of glory). A Persian, son of Pharnaces, whom he succeeded, in the reign of Darius II., as satrap of the region Dascylitis, which embraced the coast lands in Northwestern Asia Minor. In B.C. 413 he espoused the cause of the Spartans, with whom he acted in concert for several years, endeavoring to drive the Athenians from the region of the Hellespont. In 408, however, changing his policy, he made a covenant of friendship and hospitality with Alcibiades, and accepted terms of accommodation from the Athenians. In 396 he defeated an invading Spartan force under Agesilaus, but in the next year was himself defeated by that general. Soon after, Conon came to his assistance from Athens, and the two sailed through the Ægean Sea, driving out the Lacedæmonians from the seaport towns. Pharnabazus's final effort was with the Athenian Iphicrates in Egypt in 377 and the following years. The expedition proved unsuccessful.

PHA'ROS (Lat., from Gk. φάρος). A rocky island off the west extremity of the Egyptian coast, opposite the town of Rakotis. When Alexander chose this spot as the site of Alexandria, he connected the island with the mainland by the Heptastadium, or Seven-Furlong Mole. This made it possible to build two harbors, and on the eastern extremity of the island, at the entrance to the great harbor, Ptolemy I. began the erection of a great lighthouse, which was finished under his son, Ptolemy Philadelphus, about B.C. 282. The architect was Sostratus of Cnidus, and the work was reckoned among the wonders of the world. It was a lofty tower with a square base measuring about 100 feet on a side, and the light was furnished by a beacon fire on the summit. The statements that it was 400 feet high and that the light was visible for 60 miles at sea are certainly exaggerations. After standing for nearly 1600 years one side was thrown down by an earthquake on August 7, 1303, and in 1346 it was a complete ruin. In 1478 the foundations were used for the fort Kaït Baï, and the side of the great central tower has the same length as that given for the side of the old Pharos.

PHARSALIA. An epic poem in ten books by Lucan, narrating the struggle between Cæsar and Pompeius. The hero is Cato.

PHARSA'LUS (Lat., from Gk. Φάρσαλος), now PHERSALA. A Greek city of Southern Thessaly, on the river Enipeus, the chief town of the District of Pharsalia. It does not appear in history until the fifth century B.C., and seems to have been one of the prosperous cities of Thessaly. In the fourth century B.C. it was the home of Daochus, who was one of the chief adherents of Philip of Macedon. It is best known from the battle of Pharsalia, fought near the city on August 9, B.C. 48, between Cæsar and Pompeius. Pompeius had about 47,000 legionaries, 7000 cavalry, and a great number of light-armed auxiliaries. Cæsar had 22,000 legionaries, and 1000 German and Gallic cavalry. The battle, which commenced with an attack by Pompeius's cavalry on Cæsar's right wing, ended in the turning of Pompeius's left and the destruction of his army. About 15,000 fell, and the remainder surrendered on the following day. Phersala was one of the positions occupied by the Greeks in the disastrous war against Turkey in 1897, and after the rout of the Greeks was entered by the Turks on May 6th.

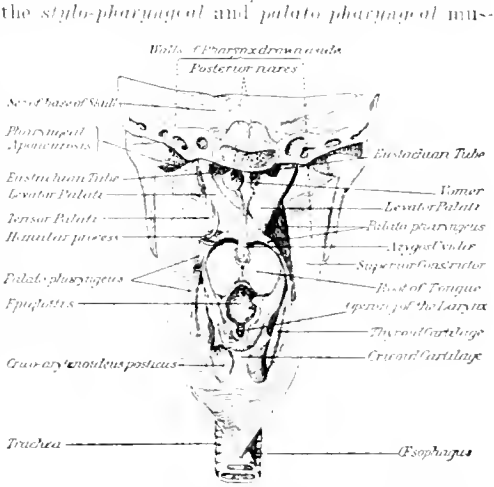
PHARYNGITIS (Neo-Lat., from Gk. φάρυγξ, *pharynx*, throat, pharynx). A disease of the mucous membrane lining the pharynx, accompanied by inflammation. It is generally described as of one of two types: (1) catarrhal; (2) follicular. Catarrhal pharyngitis is the ordinary 'sore throat.' It is characterized by swelling and laxation of the mucous membrane, with redness and tenderness of its surface, and occasionally ulceration with bleeding. Occasionally there is a chill, followed by fever at the invasion of the attack. The follicular variety is characterized by a pebbled surface, the elevations corresponding to the situation of the follicles in the membrane. Either variety may be preceded by a stage during which the mucous membrane is dry and the surface dull and pale. There is also a chronic dry pharyngitis. Pharyngitis is generally caused by inhaling irritating vapors, including tobacco smoke, exposure to chilling wind when perspiring, or by the presence of uric acid in the blood. It is increased by constipation. Internal treatment for pharyngitis includes the administration of aconite, codeine, cubeb, alkalies, sodium salicylate, quinine, and tincture of iron. Local applications include tincture of iron, glycerite of tannic acid, benzoinol, camphor, menthol, and nitrate of silver.

Inflammation of the pharyngeal soft parts around the tonsil, or peritonsillitis, is treated under QUINSY (q.v.).

PHARYNGOG'NATHI (Neo-Lat. nom. pl., from Gk. *φάρυγξ, pharynx*, throat + γνάθος, *gnathos*, jaw). A suborder of acanthopterous fishes, having the lower pharyngeals fully united. It includes the Labridæ, Scaridæ, and allied families. This group has aroused great diversity of opinion among ichthyologists. Consult Jordan and Evermann, *Fishes of North America* (Washington, 1896).

PHARYNX (Neo-Lat., from Gk. φάρυγξ, throat, pharynx; connected with φαραγξ, *pharanx*, cleft, φαρᾶν, *pharan*, to plow). The name of the combined portion of the respiratory and alimentary tracts which lies behind the nose and mouth above and in front, and the larynx and œsophagus below. It is a musculo-membranous sac, situated in front of the cervical portion of the vertebral column, and extending from the base of the occiput to the level of the fifth cervical vertebra, where it becomes continuous with the œsophagus (q.v.). Its length is about four inches and a half; it is broader in its transverse than in its antero-posterior diameter, and its narrowest point is at its termination in the œsophagus. Seven openings communicate with it, viz.: the two *posterior nares* or nostrils, at the upper and front part of the pharynx; the two *Eustachian tubes*, opening on the outer margins of the preceding orifices; the *mouth*; the *larynx*; and the *œsophagus*.

The pharynx is composed of an external *muscular* coat; a middle *fibrous* coat called the *pharyngeal aponeurosis*, thick above where the muscular coat is absent, and gradually thinning as it descends; and a *mucous* coat, continuous with the mucous membrane of the mouth and nostrils. The muscular coat requires special notice. It is composed of a *superior, middle*, and *inferior constrictor* muscle on either side, together with two less important muscles, termed the *stylo-pharyngeal* and *palato pharyngeal* mus-



cles. When the food, after being sufficiently masticated and mixed with saliva, is thrown, by the action of the tongue, into the pharynx, the latter is drawn upward and dilated in different directions; the elevator muscles (the stylo-pharyngeal and palato-pharyngeal) then relax, and the pharynx descends; and as soon as the morsel is fairly within the sphere of action of the constrictor muscles, they successively contract upon it, and gradually pass it onward to the œsophagus. Independently of its importance in the act of swallowing, the pharynx exerts an influence on the modulation of the voice, especially in the production of the higher notes.

The pharynx is subject to various circulatory disturbances, to acute and chronic inflammations, ulceration, suppuration, and abscess. It is the most frequent site of diphtheria. This affection as well as the suppurative processes requires prompt and appropriate medical treatment.

PHASCOLOGALE, fās'kō-lō-gā'lē (Neo-Lat., for **phascologale*, from Gk. φάσκωλος, *phaskōlos*, leathern bag + γαλῆ, *galē*, weasel). A genus of

diminutive. [illegible] dasyures (q.v.), very pretty, and much like mice, except that they live wholly in trees and make their homes in hollows of tree-trunks.

PHASES (ML., nom. pl., from Gk. *φασις*, *phasis*, appearance, from *φάειν*, *phaein*, Skt. *bhā*, to shine). The different luminous appearances presented by the moon and several of the planets, sometimes the whole, a part, or none, of the luminous surface being seen from the earth. (For the various phases of the moon and the seasons for them, see MOON.) Mercury and Venus present to an observer on the earth similar phases to those of the moon; but require, instead of a month, periods of 116 and 584 days, respectively, to pass through a complete series of phases. Since Mars has an orbit exterior to that of the earth, it cannot pass between it and the sun. Consequently, we can never observe a crescent phase of this planet. But when in quadrature (q.v.) it is visibly gibbous, like the moon when about four days from full. The other planets show no observable phases, on account of their great distances from the earth.

PHA'SIS. The ancient name of a river in Transcaucasia, now called the Rion (q.v.).

PHEASANT (AF. *fesant*, *fesaunt*, OF., Fr. *faisan*, from Lat. *phasianus*, from Gk. *φασιανός*, pheasant, Φασιανός, relating to the Phasis, from Φᾶσις, *Phasis*, name of a river in Colchis, where the birds are said to have abounded). A large group of handsome gallinaceous birds of the family Phasianidæ, and especially of the subfamily Phasianinæ. They have the cheeks and skin around the eyes destitute of feathers; the wings short, and the tail usually more or less elongated; and the feet of the cocks spurred. The males are always birds of splendid plumage, while the females are generally quite inconspicuous. The name pheasant was first applied to the bird now so extensively naturalized in Western Europe, and came from the Phasis River, on whose banks the birds are said to have been very abundant, and whence they were first brought to Europe before the fourteenth century. It is now the standard game-bird of Great Britain, and bred and 'preserved' for the annual shooting season in enormous numbers. The plumage of the common pheasant (*Phasianus Colchicus*) is very handsome. The head and neck of the cock are steel blue, reflecting brown, green, and purple tints in different lights; the back and wings exhibit a fine mixture of orange-red, black, brown, and light yellow; the breast and belly are golden red, each feather margined with black, and reflecting tints of gold and purple. The whole length of a male pheasant is about three feet, of which the tail often measures two feet. The entire length of the female is about two feet, and the general color is pale yellowish brown, varied with darker brown, the sides of the neck tinged with red and green. See Colored Plate of GAME BIRDS, under GROUSE.

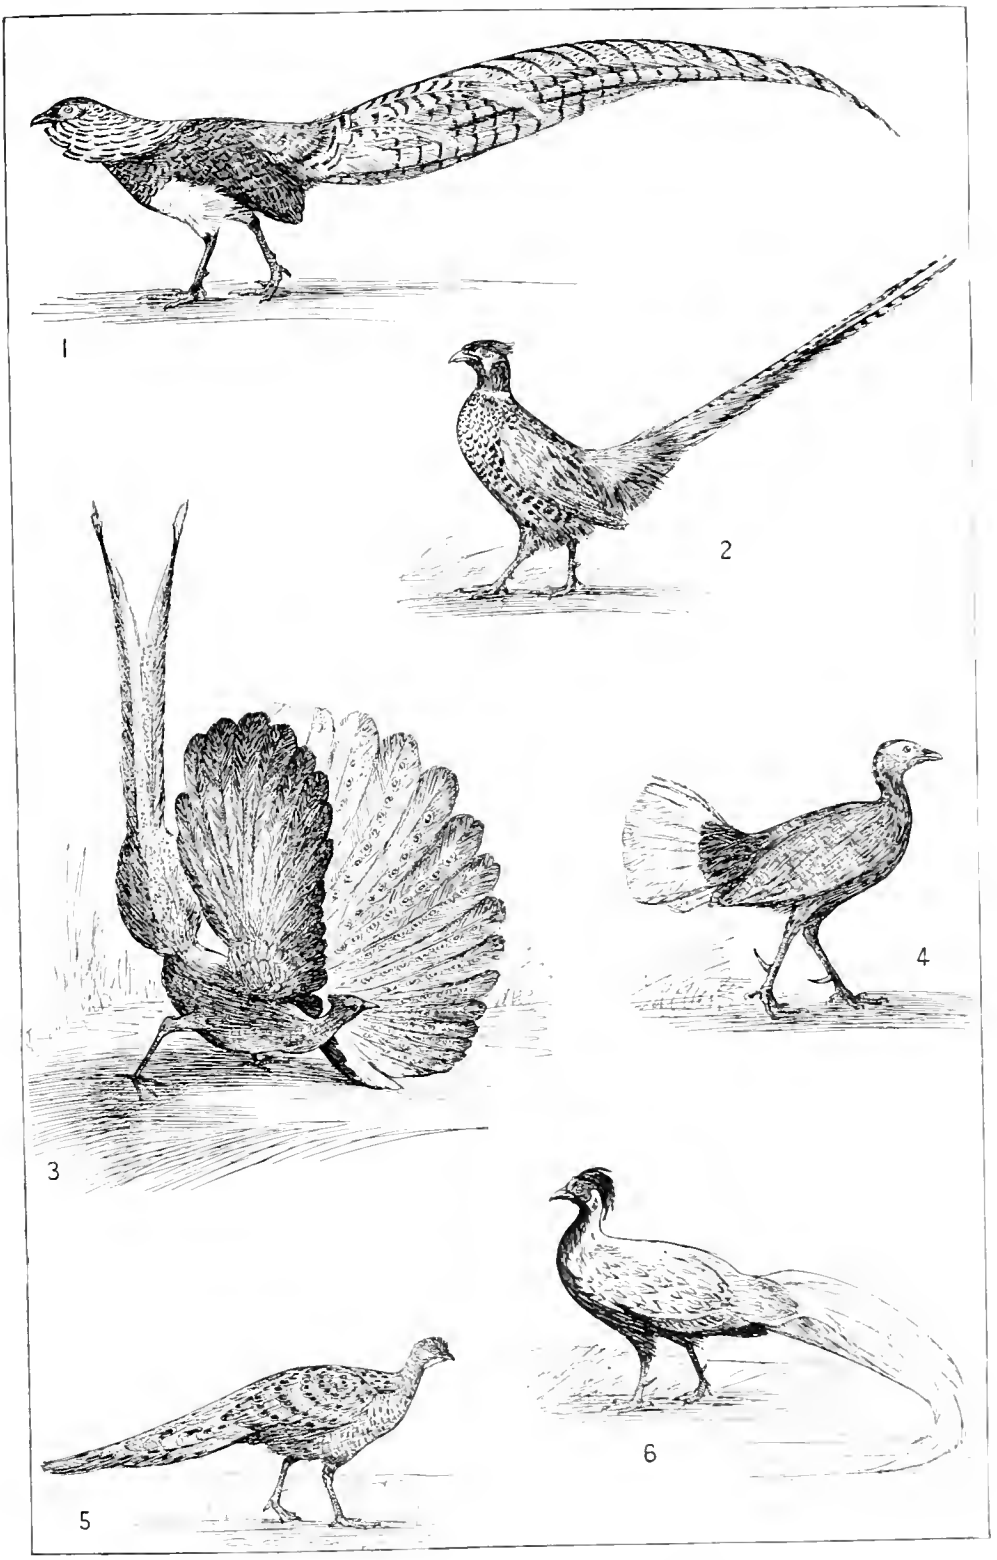
The ordinary weight of a pheasant is about two pounds and a half; but when abundantly supplied with food, and kept undisturbed, they are sometimes $4\frac{1}{2}$ pounds in weight. Pheasants, unlike grouse, are polygamous.

The nest of the pheasant is on the ground, and is a rude heap of leaves and grasses, in which eleven or twelve olive brown eggs are laid. But in the half-domesticated state in which the bird exists in English preserves, the eggs are taken by the gamekeeper, and hatched by hens. Very young pheasants must be carefully supplied with ants, eggs, maggots, etc., and the whole difficulty of rearing them is in their earliest stage. Adult pheasants feed indiscriminately on berries, seeds, roots, young shoots of plants, worms, insects, etc. They roost in trees. The male pheasant takes flight much more readily than the female, which often remains still until the sportsman is almost upon her. The males and females do not associate together except during the breeding season, but small numbers of one sex are often found in company. The 'short crow' of the males begins to be heard in March. In England and Scotland pheasant-shooting legally begins on October 1st and ends on February 3d. The pheasants turned out from the gamekeeper's breeding-yard into a preserve are in general supplied with abundance of food during winter, and come to the accustomed call as readily as any kind of poultry, so that the sportsmanship of a *battue*, in which they are killed by scores or hundreds, is of the lowest kind. The pheasant exhibits a remarkable readiness to hybridize with other gallinaceous birds; a hybrid between it and the common fowl is not infrequent, and is called a *pero*. Hybrids with the black grouse have also occurred. The flesh is excellent for eating.

The common pheasant is typical of the whole group. The genus Phasianus contains some fifteen other species, all natives of Central or Eastern Asia. Of these, Reeve's pheasant of Northern China is a large bird with notably white and edible flesh. The general color is golden yellow, each feather barred with black; the flanks are white with a chestnut margin, and the belly is black. The tail is extremely long, the central feathers sometimes measuring five or six feet; they are white margined with buff and barred with black and chestnut. Wallich's pheasant, the 'cheer' of the sportsmen of Northeastern India, is another large species, found only at elevations above 4000 feet, and remarkable because both sexes crow. It has a long dark-brown crest, and the general color is yellowish-brown, rufous and ashy, more or less barred with black. The Mongolian pheasant (*Phasianus Mongolicus*), the green-breasted pheasant (*Phasianus versicolor*), and Soemmering's pheasant (*Phasianus Soemmeringii*) are of special interest because they have been introduced into various parts of the United States. In Oregon they are so abundant in many places as to be a nuisance.

Four other genera are included in the Phasianinæ. Of the genus Ithogines, known as 'blood' pheasants, three species are alpine birds of the Himalayas and China. They are remarkable for their hardiness, living close to the limits of perpetual snow, and for the large number (three to five) of spurs on the tarsus of the male. The genus Euplocomus (or Gennæus) contains 14 species, known as 'fire-back' (or Macartney), 'kaleege,' and 'silver' pheasants. They are birds of very rich plumage, the lower back being fiery, metallic red; the bare skin of the head is deep blue or red. They are natives of Southeastern Asia and range from Formosa to Sumatra. Some of the fire-backs have short, square tails in both sexes, while others have the broad, elongated tails. The Chinese silver pheasant (*Gennæus nycthemerus*) is a good ex-

PHEASANTS



1. LADY AMHERST'S GOLDEN PHEASANT (Chrysolophus Amherstiæ).
2. COMMON PHEASANT (Phasianus Colchicus).
3. ARGUS PHEASANT (Argusianus giganteus).
4. BORNEAN PHEASANT (Lobiophasis Bulweri).
5. PEACOCK PHEASANT (Polyplectron bicalcaratum).
6. CHINESE SILVER PHEASANT (Gennæus nycthemerus).

ample of that group: the upper parts and tail are white, more or less finely mottled with black, while the under parts are bluish-black. They are forest-loving birds and not gregarious. The kaleege pheasants are generally dark-colored, with long pendent crests; the tail is usually bluish-black. The third genus contains only one species, the remarkable Bulwer's pheasant (*Lobiophasis Bulweri*) from Borneo. There are three pairs of peculiar outgrowths of nude skin on the head; the plumage is metallic of various hues; and the tail, which is made up of thirty rather stiff feathers, bare near the tip, is pure white. In the female the tail contains only twenty-eight feathers. Allied to these is the Impeyan pheasant (*Lophophorus Impeyanus*).

A very striking form, often seen in menageries and private parks, is the Indo-Malay Argus pheasant (*Argusianus giganteus*), which has not only a long and splendidly ocellated tail, but the secondaries of the wings are enormously developed; the way in which these ornamental feathers are displayed in the courting season appears in the illustration of this species on the Plate of PHEASANTS.

The species of Chrysolophus includes some very gorgeous birds. The type (*Chrysolophus pictus*) has the back metallic green, the under parts scarlet, the rump golden-yellow, the crest amber-colored, and a ruff about the neck orange-red tipped with blue, while the Lady Amherst pheasant (*Chrysolophus Amherstiæ*) has the breast metallic green and the belly white, the crest crimson with white tips, and the ruff white margined with deep green. Lady Amherst's pheasant also has an excessively long tail. Little is known about these pheasants except that they are very hardy birds, living in thick woods on the mountains at moderate heights. They are extremely jealous birds, and though both occur in China, they are not found in the same valleys nor on the same mountains, but keep entirely separate.

The peacock-pheasants comprise a large number of species found from India to China and on the Malayan islands, and are gorgeously colored, with many peacock-like 'eyes' on the tail-feathers of the males.

Several more or less related birds are called 'pheasants' by colonists and sportsmen in various parts of the world, e.g. our ruffed grouse in the Southern United States.

Consult: Evans, *Birds* (London, 1903); Stejneger, *Standard Natural History*, vol. iv. (Boston, 1885); Elliot, *Monograph of the Phasianidæ* (colored plates, London, 1870-72); Tegetmeier, *Pheasants: Their Natural History and Practical Management* (ib., 2d ed., 1881).

PHEASANT'S-EYE. See ADONIS, and Plate of ACANTHUS.

PHEASANT-SHELL. A gastropod mollusk of the family Turbinidæ, of which the shells are much valued for their beauty, suggesting, by their gorgeous metallic tints, the plumage of pheasants; when, formerly, they were rare in collections, they were sometimes sold for extraordinary prices. They are now comparatively cheap and plentiful, being found in great numbers in Australia.

PHÈDRE, fā'dr'. A tragedy in five acts by Racine, first presented at the Hôtel de Bourgogne in 1677. The subject is taken from the *Hippolytus* of Euripides. Phèdre is represented as experiencing all the phases of profound passion, with an underlying moral sense which produces poignant remorse and repentance. The character is one of the strongest in the French drama. The play was translated into German iambics by Schiller in 1805.

PHE'GEUS (Lat., from Gk. *Φηγεύς*). An Arcadian king who gave his daughter in marriage to Alcmæon. The latter gave his wife the peplus and necklace of Harmonia, but was slain by the sons of Phegeus when he attempted to recover his gifts in order to give them to his later wife, Calirrhoë. Phegeus in turn was killed by the sons of Alcmæon.

PHEI'DIAS. See PHIDIAS.

PHELLODERM (from Gk. *φελλός, phellos*, cork + *δέρμα, derma*, skin). The plant tissue produced internally by the phellogen (q.v.). See HISTOLOGY.

PHELLOGEN (from Gk. *φελλός, phellos*, cork + *-γενής, -genēs*, producing, from *γίγνεσθαι, gignesthai*, to become), or CORK CAMBIUM. A zone of actively dividing cells which give rise externally to the cork tissue (periderm), and internally to secondary cortex (phellodern) of the bark. See HISTOLOGY.

PHELPS, ANSON GREENE (1781-1853). An American merchant and philanthropist, born in Connecticut. He removed to Hartford at the age of eighteen, and established himself in the saddlery business. In 1815 he removed to New York, and engaged as a merchant in tin plate and heavy metals. He accumulated a large fortune, partly by investments in real estate, and devoted a large part of his property to benevolent purposes. He was president of the blind asylum, of the American Board of Commissioners for Foreign Missions, and of the New York branch of the Colonization Society. He bequeathed to religious and charitable institutions $371,000, and intrusted to his son a fund of $100,000, to dispose of in charity. Ansonia, Conn., was named in his honor.

PHELPS, AUSTIN (1820-90). An American clergyman and author. He was born at West Brookfield, Mass., entered Hobart College at the age of thirteen, studied at Amherst and the University of Pennsylvania, and took his degree from the latter in 1837. After further study at the university, at Union Theological Seminary, and at the Yale Divinity School, in 1842 he became pastor of the Pine Street Congregational Church in Boston, where he remained until 1848, when he accepted the chair of sacred rhetoric at Andover Theological Seminary. He remained here for thirty years, assuming in 1869 the presidency in connection with the work of his professorship. In 1879 he resigned both positions because of ill health, and thereafter lived in retirement, though freely contributing, mainly through the columns of *The Congregationalist*, to current theological discussions. He published several devotional works, and a number of volumes which were the outgrowth of his professional duties, among which may be mentioned *Studies of the Old Testament* (1879); *The Theory and Practice of Preaching* (1881); *English Style in Public Discourse* (1883); *Men and Books, or Studies on Homiletics* (1882); *My Study and Other Essays* (1885); *My Note-Book: Fragmentary Studies in Theology and*

[illegible] 1889). Consult his [illegible] Elizabeth Stuart Phelps Ward (New York, 1891).

PHELPS, Edward John (1822-1900). An American political leader and diplomat, born at Middlebury, Vt. He graduated at Middlebury College in 1840, and three years later was admitted to the bar in his native town. In 1845 he removed to Burlington, where he remained until 1851, when he was appointed Second Comptroller of the United States Treasury. He was then a pro-slavery Democrat, and was afterwards a strong opponent of the Civil War. In 1870 he was a member of the Vermont Constitutional Convention. Ten years later he was elected president of the American Bar Association, and in 1881 was appointed Kent professor of law at Yale. This position he held until his death. For a while he was absent from his chair when President Cleveland appointed him Minister to the Court of Saint James's. In 1893 he was appointed senior counsel for the United States in the Bering Sea arbitration. Among his publications are *The Life and Character of Charles Linsley*, and a posthumous collection of his *Orations and Essays* (1901), edited by J. G. McCullough, to which is prefixed a *Memoir* by J. W. Stewart.

PHELPS, Elizabeth Stuart (1815-52). An American author, the daughter of Prof. Moses Stuart of Andover Theological Seminary, and wife of Prof. Austin Phelps of the same institution. She was born in Andover, Mass. Her tales of New England and chiefly of clerical life showed considerable promise. Her *Sunnyside* (1851, republished in Edinburgh as *Manse of Sunnyside*) was remarkably popular.

PHELPS, Elizabeth Stuart (1844—). An American author. See Ward, Elizabeth Stuart Phelps.

PHELPS, John Wolcott (1813-85). An American soldier, born at Guilford Centre, Vt. He graduated at West Point in 1836, and soon thereafter participated in campaigns against the Creeks and Seminoles. During the Mexican War he was engaged in several of the most important battles, and in 1850 was commissioned captain of the Fourth Artillery. In 1859 he resigned from the army, but on the outbreak of the Civil War entered the Federal service as colonel of the First Vermont Volunteers. On May 17, 1861, he was commissioned brigadier-general of volunteers, and was sent to occupy Newport News. He took military possession of Ship Island, Miss., in November, 1861, and coöperated with Farragut in opening up the Lower Mississippi in April, 1862. After the occupation of New Orleans he, on his own initiative, organized the first negro troops enrolled for service in the Federal armies. This action caused great excitement among the Confederates, whose Government on August 21, 1862, declared him an outlaw for having organized and armed negro slaves. The authorities at Washington were not then ready to support Phelps, and ordered the troops to be disbanded and to be employed as laborers. On receiving this order General Phelps resigned, August 21, 1862, and took no further part in the war. During the latter years of his life he devoted himself to an anti-Masonic agitation, and in 1880 was nominated for the Presidency by the 'American' Party. He wrote several books, including a *History of Madagascar* (1884), and the *Fables of Florian* (1888); and translated de la Hodde's *Sociétés secrètes de France* (1864). Consult Howard, *Life and Public Services of Gen. John Wolcott Phelps* (Brattleboro, Vt., 1887).

PHELPS, Oliver (1749-1809). An American merchant and land speculator, born in Windsor, Conn. In 1788 he, with Nathaniel Gorham, contracted to buy from Massachusetts 6,000,000 acres of land in the Genesee country of New York for £300,000 to be paid in 'consolidated stock,' a scrip issued by Massachusetts and then much depreciated. This tract was included within the charter limits of both States, and by a compromise in 1786 ownership was given to Massachusetts, while New York retained the sovereignty. The Indian title to 2,600,000 acres was extinguished and a land office was opened at Canandaigua, N. Y. The rapid rise in price of the scrip made full payment impossible, and the remainder of the original tract was surrendered to the State. In 1790 Phelps sold to Robert Morris the unsold portion of the purchase, about 2,100,000 acres. In 1795, with Gideon Granger and others, he purchased from Connecticut 3,300,000 acres in Ohio, the so-called 'Western Reserve,' but soon sold his interests and returned to Canandaigua. From 1803 to 1805 he was a member of Congress, and was later a circuit judge. He took an active interest in the construction of the Erie Canal and built steamers on Cayuga Lake.

PHELPS, Samuel (1804-78). An English actor and manager, born and educated at Devonport. He made his first appearance in an amateur performance at the Olympic in 1825. After playing in the provinces he made his début in London as Shylock at the Haymarket (1837), and he appeared the same season with Macready at Covent Garden. He rivaled that actor and Charles Kean in certain Shakespearean rôles, such as Lear, Othello, Macbeth, and Antony, and was equally strong in the comic characters Falstaff, Bottom, and Christopher Sly; but his most notable achievement was his joint managership of the Sadler's Wells Theatre, Islington (1844-62), where he produced more than thirty of Shakespeare's plays, and those of other legitimate dramatists, with incalculable educational results both upon public taste and upon the actors employed. The undertaking was less successful financially after the retirement of Greenwood, the business partner (1860), and Phelps had abandoned it for a Drury Lane engagement by 1863.

PHELPS, Thomas Stowell (1822-1901). An American naval officer, born in Buckfield, Maine. He graduated at the United States Naval Academy in 1846, and saw service in the wars with Mexico and with the Indians of the Northwest coast (1855-56). He was on the Paraguay expedition (1858-59), served on the United States Coast Survey, made surveys of Southern harbors at the beginning of the Civil War (1861), and took part in several later naval engagements, especially in command of the *Juniata* before Fort Fisher (1865). He was promoted to be captain in 1871, commodore in 1879, rear-admiral in 1882, commander-in-chief of the South Atlantic squadron in 1883-84, and retired in 1885. Besides sailing directions for the Straits of Magellan, he wrote *Reminiscences of Seattle, Wash-*

ington Territory, and the United States Sloop-of-War Decatur During the Indian War of 1855-56 (1902).

PHENACETINE (from *phenol* + *acetine*). PARA-ACETPHENETIDINE. A coal-tar derivative strongly resembling acetanilid. It occurs as a tasteless and odorless, white, glossy, crystalline powder. It is slightly soluble in water and freely in alcohol. Its physiological action and uses are similar to those of antipyrin (q.v.). The after-effects of phenacetine are, however, less marked than those following antipyrin, and it is considered safer. It is chiefly employed for the relief of pain.

PHEN'ACO'DUS (Neo-Lat., from Gk. φέναξ, *phenax*, cheat + Lat. *coda, cauda*, tail). One of the earliest fossil ungulates, or hoofed mammals, skeletons of which are found in the Lower Eocene beds of Wyoming. It is one of the most primitive ungulates, belonging to the suborder Condylarthra, in which group the carpal and tarsal bones of the feet are wholly serial, and it presents some characters indicative of its creodont ancestry. It was a small animal of slender build, between five and six feet long, with small head, pig-like teeth, low fore-quarters, hind limbs that were much more powerful than the fore limbs, and with a long, slender tail. The feet were five-toed and somewhat digitigrade, and the larger size of the second, third, and fourth toes suggests that these were of more use in running than were the other two. A finely mounted skeleton of this animal is in the American Museum of Natural History in New York City.

PHENICIA, fē-nīsh'ā. See PHŒNICIA.

PHENICIN (Fr. *phénicine*, from Gk. φοῖνιξ, *phoinix*, purple-red), or PHENYL BROWN. A rich dye, first prepared by Roth in 1863 by the action of nitric and sulphuric acids on carbolic acid or phenol. It is a brown, amorphous powder, very soluble in alcohol, ether, and acetic acid, but only slightly soluble in water. It consists of two coloring matters, one yellow, the other a black, humus-like body. The exact chemical composition of the dye is unknown. It was formerly much used in coloring leather.

PHENOCRYST (from Gk. φαίνειν, *phainein*, to show, appear + κρύστ-αλλος *krust-allos*, crystal). The name used in petrology to designate crystal individuals in a rock that possesses more perfect boundaries and are of larger size than the remaining constituents. A rock containing such crystals is said to have a porphyritic texture. They indicate that a rock has passed through two stages of crystallization, the first leading to the formation of the phenocryst and the second to the formation of the ground mass. The first stage generally takes place while the rock mass exists in a molten condition within the earth; while the ground mass is the result of rapid cooling after the rock has been erupted.

PHENOLOGY (abbreviation of *phenomenology*, from Gk. φαινόμενον, *phainomenon*, phenomenon, nom. sg. neu. of pres. part. mid. of φαίνειν, *phainein*, to appear — -λογία, *-logia*, account, from λέγειν, *legein*, to say). That branch of ecology in which attempts are made to determine the influence of climatic factors on plant life by means of meteorological observations. See DISTRIBUTION OF PLANTS.

PHENOLS (Fr. *phénol*, from Gk. φαίνειν, *phainein*, to appear). An interesting class of carbon compounds, the simplest of which is ordinary carbolic acid (q.v.). The phenols are derivatives of benzene, and they are characterized chemically by one or more hydroxyl groups attached immediately to the so-called benzene nucleus (a ring made up of six atoms of carbon). The phenols are distinguished from the alcohols (q.v.) by having the properties of acids. Thus, unlike the alcohols, they combine with metallic hydroxides to form phenates (the alcohols form alcoholates with the alkali metals themselves, but not with their hydroxides). On the other hand, they are distinguished from acids by containing no carboxyl group (COOH) and by being weaker than the weakest carboxylic acid known, viz. carbonic acid. Their weakness as acids may be readily demonstrated by passing a current of carbonic acid gas into a solution containing, say, some phenate of sodium; the carbonic acid will then take the sodium away from the phenol, sodium carbonate will be formed, and the phenol will be set free. Among the characteristic reactions of the phenols must also be mentioned the fact that they all give colorations with ferric chloride. The principle on which fatty alcohols, phenols, and aromatic alcohols are classified and distinguished from one another symbolically, may be seen from the following formulas, showing simple representatives of the three classes in question:

CH_3OH	C_6H_5OH	$C_6H_5CH_2OH$
Methyl alcohol (fatty)	Carbolic acid (a phenol)	Benzyl alcohol (aromatic)

The distinction between the fatty alcohol and the other two substances is in the hydrocarbon radicals which hold the hydroxyl groups; the distinction between the phenol and the aromatic alcohol is in the fact that in the former the hydroxyl group is attached directly to one of the atoms of the group C_6, while in the latter the hydroxyl is linked to the C_6 ring by the group CH_2. See ACIDS.

PHENOMENON. A philosophical term meaning appearance (q.v.).

PHENYL (from *phenol*), C_6H_5. A chemical radical, i.e. a group of atoms possessed in common by the molecules of different compounds, but incapable of independent existence. See CARBON COMPOUNDS.

PHE'RÆ (Lat., from Gk. Φεραί). An ancient city of Southeastern Thessaly, about ten miles west of its harbor, Pagasæ, at the head of the Pagasæan Gulf; in Greek legend, the ancient royal seat of Admetus and Alcestis. In the early part of the fourth century B.C. the power was in the hands of Jason, son of Lycophron, who had become tyrant about the close of the Peloponnesian War. Jason was a man of marked ability, and by B.C. 374 had forced his recognition as chief of the Thessalians, and began to play an important part in the affairs of Greece, while it was said that he meditated the invasion of Persia. He was assassinated in B.C. 370. His nephew, Alexander, succeeded to his rule, but was soon confined by the Thebans to the tyranny over Pheræ. After displaying the utmost cruelty for eleven years, he was finally murdered by his wife's brothers, B.C. 357. Five years later Pheræ, with the rest of Thessaly, became subject to Philip of Macedon. At Pheræ

the [illegible] a fountain, spring, and Hyperia, famous for its reading virtues, which still flows in the centre of the modern village of Velestino.

PHERECRATES. fĕ-rĕk'ra-tēz (Lat., from Gk. *Φερεκράτης, Pherekratēs*). One of the most eminent writers of the Old Attic Comedy; a contemporary of Cratinus, Crates, Eupolis, Plato, and Aristophanes. He invented the *Pherecratean* metre (⏑ – ⏑ – ⏑ –), which is frequently used in the choruses of the Greek tragedies and in Horace. A few fragments and the titles of eighteen of his plays are extant. Consult: Meineke, *Fragmenta Comicorum Græcorum* (Berlin, 1839); and Kock, *Comicorum Atticorum Fragmenta* (Leipzig, 1880). Among the ancients he was famed for his wealth of invention and the purity of his Attic Greek.

PHERECYDES. fĕ-rĕs'i-dēz (Lat., from Gk. *Φερεκύδης, Pherekydēs*). (1) One of the earliest writers of Greek prose. He was born in the island of Syros, and flourished in the sixth century B.C. He composed a cosmogonic work on nature and the gods, entitled Πενταέμυχος (*Pentaemychos*), because, according to its doctrine, five elements made up the universe, ether, fire, air, water, and earth. That he taught Pythagoras his doctrine on the transmigration of souls may well be doubted. A fragment on the sacred marriage of Zeus and Chthonia has recently been discovered in Egypt: published by Grenfell, p. 22, *New Classical Fragments* (Oxford, 1897). The fragments formerly known, together with those of the following author, are published by Müller, *Fragmenta Historicorum Græcorum* (Paris, 1850).

(2) A logographer and native of Leros, who flourished in the middle of the fifth century B.C. He spent the greater part of his life at Athens, where he wrote his Genealogies or Autochthones (Γενεαλογίαι or Αὐτόχθονες), a work of ten books in the Ionic dialect on the descent of the gods and the noble Greek families. The extant fragments are published as indicated under (1) above. Consult, also, Luetke, *Pherecydea* (Göttingen, 1893).

PHERETIMA. Wife of Battus III. and mother of Arcesilaüs III., kings of Cyrene. To avenge the murder of her son by the Barcæans, she induced the Persian viceroy in Egypt to attack their city. After the city fell she caused those chiefly responsible for her son's death to be impaled and the breasts of their wives to be cut off.

PHERSA'LA. The modern name of the Greek city Pharsalus (q.v.).

PHI BE'TA KAP'PA FRATERNITY. A society which derives its name from the initials of the three Greek words φιλοσοφία βίου κυβερνήτης, (Philosophy the Guide of Life). It was formed at the beginning of the Revolutionary War (December 5, 1776), in William and Mary College, at Williamsburg, Va. It is the oldest of the so-called Greek letter societies. Its original purposes were the encouragement of patriotism and scholarship, and especially of literature. Within five years chapters were established in Harvard and Yale, and still later before the close of the century) in Dartmouth. In recent years, the number of chapters has been greatly enlarged. With varying periods of energy and inertia, the society has existed until this day, when it is more extended and [illegible] than ever. Its anniversaries, usually observed at commencement, but not always, have been marked by the delivery of orations and poems, and frequently by banquets with post-prandial speeches. Many of the foremost speakers of the country have appeared on these occasions. Membership in the fraternity is conferred upon those undergraduates who are among the best scholars, and honorary members, later in life, are occasionally chosen from among the scholars of the country not previously elected. The secrecy of the original society was abandoned at the time of the anti-Masonic agitation. The members are entitled to wear as a badge a gold watchkey with simple emblems and inscriptions. See Plate COLLEGE FRATERNITIES, under FRATERNITIES). The following is a list of the different chapters and the dates of their establishment: William and Mary (1776), Yale (1780?), Harvard (1780?), Dartmouth (1787), Union (1817), Bowdoin (1824), Brown (1830), Trinity (1845), Wesleyan (1845), Western Reserve (1847), Vermont (1848), Amherst (1853), Kenyon (1858), New York University (1858), Marietta (1860), Williams (1864), New York City College (1867), Columbia (1868), Middlebury (1868), Hamilton (1869), Rutgers (1869), Hobart (1871), Colgate (1875), Cornell (1882), Dickinson (1886), Lehigh (1886), Rochester (1886), De Pauw (1889), Lafayette (1889), Kansas (1889), Northwestern (1889), Minnesota (1892), Pennsylvania (1892), Tufts (1892), Colby (1895), Iowa (1895), Johns Hopkins (1895), Nebraska (1895), Swarthmore (1895), Syracuse (1895), Boston University (1898), California (1898), Chicago (1898), Cincinnati (1898), Haverford (1898), Princeton (1898), Saint Lawrence (1898), Vassar (1898), Wabash (1898), Wisconsin (1898), Allegheny (1901), Missouri (1901), and Vanderbilt (1901).

In 1881, at the instance of the Harvard chapter, delegates met, and after some preliminary discussion a call was issued for a general body, which convened in Saratoga on September 5, 1883, when delegates from sixteen chapters ratified the constitution, organizing a National Council, consisting of twenty senators, and delegates not exceeding three in number from the several chapters of the society. The influence of this national body is chiefly directed toward the establishment of uniform customs with regard to membership and practices. Under its supervision a general catalogue, containing in some form the names and addresses of 17,000 members of the society, has been prepared.

PHIDA'RI. A river in Ætolia, Greece. It rises in the Vardusia Mountain and, after a southwesterly course of about 65 miles, flows into the Gulf of Patras.

PHID'IAS, or **PHEI'DIAS** (Lat., from Gk. *Φειδίας*,). The greatest sculptor of ancient Greece, born in Attica, probably between 500 and 490 B.C., the son of Charmides. His master seems to have been the Athenian Hegias, famous for his statues of divinities, and some late authorities also connect him with the Argive Hagelaïdas; but both these statements have been questioned, and in general the information as to his life is scanty and often contradictory. Interest in the lives of the great artists arose comparatively late, when accurate information was scarcely attainable. For our knowledge of his works we are dependent on the statements of ancient writers,

as no certain original from his hand has survived. The descriptions, however, warrant the assignment to him of the originals from which several marbles were copied, and to his designs are probably due the Parthenon sculptures, though none of them can with certainty be attributed to his hand. The unanimous testimony of the ancients and the evidence of the monuments mark him as the typical artist of the best culture of Greece. His genius found the soil for its ripest expression in the Athens of Pericles, and his works stand with the tragedies of Sophocles as the most perfect expression of the spirit of the noblest period of Greek civilization. Noble ideals and a thorough mastery of technique enabled him beyond any other ancient artist to present beauty in its purity and completeness. In his works we find incorporated the desire of Greek art to reproduce the ideal beauty which lies behind the realities of nature, and which while holding fast to truthful expression seeks to show forth the typical and permanent elements rather than the individual and transitory. This endeavor to express the sublime ideals formed within the soul was recognized by the ancients as the source from which came the inspiration for the colossal statue of Zeus at Olympia, which the artist was said to have drawn from Homer (*Iliad*, i. 529), and which seemed to incorporate the divine majesty, power, and loving kindness. In all the branches of sculpture we find Phidias celebrated. In bronze were wrought the Athena of the Lemnians, probably represented in a statue at Dresden and a head at Bologna, and the colossal Athena sometimes called the Promachos, which ancient tradition at any rate attributed to him; in marble, an Aphrodite in Athens, and the face, hands, and feet of an Athena at Platæa, whose drapery was of gilded wood, thus forming a cheap substitute for the chryselephantine technique in which he attained his greatest fame. His earliest work in this style was an Athena at Pellene in Achæa, but his most celebrated were the Zeus at Olympia and the Athena of the Parthenon. In this style a core of wood was overlaid with ivory to represent the flesh, and gold, often inlaid with enamel, for drapery. On the Parthenos the gold was detachable and valued at 44 talents. The Zeus at Olympia represented the god seated on his throne, on his head a wreath of olive, in his left hand the sceptre crowned with an eagle, while on his extended right stood a Nike (Victory) holding a fillet. The throne was elaborately decorated with figures in relief and in the round. Our only knowledge of this statue is from descriptions and representations on late coins of Elis, which are, of course, far too small to give any satisfactory idea of its appearance. It may be added that the so-called Zeus Otricoli of the Vatican is certainly not Phidian. The Athena Parthenos was a standing figure. In her left hand the goddess held her lance and at her left side stood the shield. The extended right hand also held a Nike, and was perhaps supported by a pillar. Here, too, the shield, the pedestal, the helmet, and even the soles of the sandals were decorated with scenes from Grecian legend. This statue was erected in B.C. 438, and if Phidias supervised the decorations of the Parthenon he must have worked in Athens from about B.C. 447 to 433, for the building was not completed before this date.

The chronology and events of the closing years of his life are much disputed and the ancient testimony is conflicting. All accounts agree that he was tried at Athens for embezzling the gold appropriated for the statue; but, while one account says he died in prison, another says he was banished, went to Elis, made the Zeus, and was then accused and put to death by the Eleans. This last can scarcely be right, as we know his descendants enjoyed hereditary honors at Olympia. The most probable theory is perhaps that the statue of Zeus was made just after the middle of the fifth century B.C., and that after that the artist remained in Athens. It may be regarded as certain that he shared in the attack on the friends of Pericles, and the account may be true that, while acquitted of the charge of embezzlement, he was condemned for impiety in introducing his portrait on the shield of the Parthenos. Many competent archæologists, however, prefer to date the Zeus later than the Parthenos. In addition to the histories of Greek sculpture cited under GREEK ART, consult: C. O. Müller, *De Phidia Vita et Operibus* (Göttingen, 1827); Petersen, *Die Kunst des Phidias* (Berlin, 1873); Collignon, *Phidias* (Paris, 1886); Waldstein, *Essays on the Art of Phidias* (Cambridge and New York, 1885); Furtwängler, *Masterpieces of Greek Sculpture*, trans. by E. Sellers (London and New York, 1895), of great value for the attribution of extant marbles to Phidian originals, but to be used with caution; *Phidias* in "Masters in Art Series" (Boston, 1902), with good bibliography. For the death of Phidias, see, in addition: Loescheke, "Phidias' Tod," in *Historische Untersuchungen* (Bonn, 1882); Schöll, "Der Prozess des Phidias," in *Sitzungsberichte der Münchener Akademie* (Munich, 1888).

PHI'DON. Son of Aristodamidas and King of Argos, eighth century B.C. He restored several towns to the kingdom, but did not succeed in his ambition to extend his authority throughout the Peloponnesus. He is best remembered for the introduction of copper and silver coinage and of a new scale of weights and measures. This system, which finally was used throughout the larger part of Greece, was known as the Aeginetan, from Aegina, whose inhabitants through their commerce did most to extend its use.

PHIGA'LIA. A town of ancient Arcadia, now in the Olympia district of the province of Messenia, 25 miles northwest of Messene. Near by are the falls of Neda. In B.C. 659 Phigalia was taken by the Spartans, but later became free. Its celebrity in modern times is due to the ruins of a magnificent temple on Mount Cotylium at Bassæ in the commune of Phigalia and about four miles from the town proper. See PHIGALIAN MARBLES.

PHIGALIAN MARBLES. The sculptured frieze taken from the interior of the cella of the temple of Apollo at Phigalia, in Arcadia in 1814, and transferred to the British Museum. It represented the contest between the Centaurs and Lapithæ and the Greeks and Amazons. The temple is situated in the extreme southwest of Arcadia, about four miles from Phigalia, on a terrace on the side of a mountain in a picturesque and wild country, and had been completely forgotten till it was accidentally discovered in 1765 by a French architect, Bocher, and soon after was visited and described by the English traveler Chandler, who was followed by Gell, Dodwell, and

[illegible] 1812 it was carefully examined by English and German artists [illegible], the results of whose investigations [illegible] in Stackelberg, *Der Apollo Tempel zu Bassä in Arkadien* (Rome, 1826), and Cockerell, *The Temples of Jupiter Panhellenius at Ægina and Apollo Epicurius at Bassæ, Near Phigaleia, in Arcadia* (London, 1860). The temple is of a soft yellowish brown limestone and is a Doric hexastyle peripteros with fifteen columns on the sides, about 125 feet long and 46 feet wide. Owing to the nature of the ground, it stands north and south, but there is a small side door in the east wall of the cella, opposite the cult statue. Of the 38 columns, 35 are still standing and support much of the architrave, though the pediments and ceiling have fallen. The fallen members lie about the ruin, which seems to have been largely caused by Christian iconoclasm and greed for the metal clamps by which the stones were held. The partial restoration from the existing remains is planned (1903) by the Greek Archæological Society. The sculptures show great skill and boldness in design, but the execution is by no means so praiseworthy, as the proportions are often bad and the faces dull. As the temple was the work of Ictinus, the architect of the Parthenon, it is very probable that the sculptures were designed by an Athenian artist, but the carving is probably the work of less experienced Arcadian sculptors. The fragmentary sculptures on the metopes of the pronaos and opisthodomos are of rather better workmanship. In addition to the general works cited under GREEK ART, by Collignon, Overbeck, Mitchell, and Murray, consult the article "Phigaleia" in Baumeister, *Denkmäler des klassischen Altertums* (Munich, 1889); and Smith, *Catalogue of the Sculptures in the British Museum* (London, 1892).

PHI'LA. Daughter of Antipater, regent of Macedonia. She was celebrated as one of the noblest women of her time. In B.C. 322 she was married to Craterus. He died in about a year, and Phila was then married to the son of Antigonus, Demetrius, whose varying fortunes she shared. When Demetrius was banished from Macedonia in B.C. 287, Phila killed herself at Cassandrea. She left two children by Demetrius, Antigonus and Stratonice. The son, surnamed Gonatas, became King of Macedonia; Stratonice became the wife of Seleucus and subsequently of his son Antiochus.

PHILADEL'PHIA (Lat., from Gk. Φιλαδελφεία, *Philadelpheia*, named in honor of Attalus Philadelphus). A city of Asia Minor, now called Alasheir (the 'reddish city,' from the color of the hillsides in the region), situated in the valley which runs inward from the Gulf of Smyrna, about 75 miles east by south of Smyrna (Map: Turkey in Asia, C 3). The city was founded in the second century B.C. It lay on the trade routes from the interior to the coast and assumed a position of commercial importance. Its name was changed at different times, as shown by the coins of Roman emperors, and it was a point of considerable importance in the political affairs of the Province of Asia. Philadelphia was the head of a district in which Christian churches were established very early, since messages were sent to it in the Book of Revelation (iii, 7-13). Little is known concerning [illegible] or size of these churches. Philadelphia [illegible] part in later history, figuring as a bulwark against the Turks. See ALASHEIR.

PHILADELPHIA. The chief city of Pennsylvania, and the third city in population and importance of the United States, co-extensive with Philadelphia County, having an area of 129.5 square miles. It is situated in the southeastern corner of the State, at the confluence of the Schuylkill with the Delaware, about 50 miles from the mouth of the Delaware and 100 miles from the Atlantic Ocean, in latitude 39° 57′ N. and longitude 75° 9′ W. It is distant from New York by rail 90 miles, from Washington 132, and from Chicago 822.

The climate of Philadelphia is considerably milder in winter and warmer in summer than that of the central and western cities of the State. The mean temperature for January is 32.3°, and for July 76.2°. The heat during July and August is often very intense, the temperature rising sometimes above 100°. The average annual rainfall in the city is about 44 inches, slightly heavier than that of New York.

DESCRIPTION. William Penn founded the city on the narrow neck of land, some two miles wide, lying between the Delaware and Schuylkill rivers. Disregarding his plan for a simultaneous growth of the city backward from each river, the early settlers preferred to remain near the Delaware, along which occurred the first north and south expansion of the city. It was not until the beginning of the nineteenth century that the westward growth of the city reached Broad Street, the half-way line to the Schuylkill. From this time on the city has grown more rapidly, extending southward to the junction of the two rivers, westward far beyond the Schuylkill to Cobb's Creek, and northward in two main branches, the easternmost following the Delaware to Poquessing Creek, eighteen miles from the southern limit, and the westerly through the suburban region stretching ten miles along the Wissahickon—a tributary of the Schuylkill. In the western and northern sections of the city large areas of open country still exist. From the dike-protected lowlands of the south, five feet below the average high tide, the city rises gradually to heights of 443 feet in the hilly regions of the northwest. The general plan of the streets is determined by the east and west direction of Market Street, the main business thoroughfare, 100 feet wide, which runs directly west from the Delaware, a distance of six miles, separating the city in respect of street numbering into north and south divisions; and by Broad Street, 113 feet wide and 12 miles long, which at City Hall Square intersects Market at right angles. The main portion of the city is laid out with great regularity, the numbered streets running parallel with Broad, and the named streets with Market. The regularity of the general plan is broken, however, in the portion east of the Schuylkill, by Ridge and Germantown avenues, which intersect diagonally the streets north of Market, and by Passyunk and Moyamensing avenues, south of Market Street; in West Philadelphia, Lancaster Avenue, north, and Woodland Avenue, south of Market Street, act in a similar manner, though in this and in other outlying sections there is, in general, less attempt to follow strictly the regularity of the older portions of the city. There are more than 1560 miles of streets, of which

some 900 miles are paved with brick, stone, or asphalt, 225 macadamized, and the remainder unpaved. The mileage of sewers is 951 and of water mains 1319. The street railways (employing the overhead trolley system, and in 1902 carrying 325,801,963 passengers) have a total mileage of 475, and the steam railroads of 360. At the present time (1903) there is under construction a subway system of four tracks from the Delaware to the Schuylkill, with an elevated extension along Market Street from the Schuylkill to the city line. Twelve public and twelve railroad bridges cross the Schuylkill, and one railroad bridge the Delaware; and among these are some of the finest structures of the kind in the country.

It is possible to characterize with tolerable accuracy the various sections of Philadelphia. The business life centres around Market Street. The portion north and south of this thoroughfare bordering the Delaware is devoted to wholesale trade, shipping, and warehouses; from Third Street to Eighth, Market, Chestnut, and Walnut may be designated as the financial and banking centre of the city; these streets, with Arch, from Eighth to City Hall, form the great retail shopping section, where are found the great department stores. The large office buildings cluster about the City Hall, at the junction of Broad and Market Streets, in the vicinity of which are also found the Pennsylvania and Reading depots and the Baldwin Locomotive Works. Westward from the City Hall, Market Street is lined by smaller wholesale and retail establishments; while beyond the Schuylkill, Lancaster and Woodland avenues dispute its supremacy in retail trade. The northeastern section, comprising Kensington and Frankfort, and certain portions of the northwest section form the chief textile centre of the city; the northeast section at Port Richmond is also the location of Cramp's ship-yards. The southern portion, east of the Schuylkill, is devoted to general manufactures and to transportation.

The residential portions of the city seem to be as clearly divided by Market Street as are the business interests. South of that thoroughfare, on Chestnut, Walnut, and Spruce streets, centring about Rittenhouse Square, is the aristocratic residential section of the city. North of Market the upper portion of Broad Street, with portions of other streets between it and the Schuylkill, forms another important residence area. North of this comes the residential section occupied largely by textile operatives. South of Market and extending a few blocks below Lombard is the section occupied by the foreign and colored elements, with the former, consisting largely of Italians and Hebrews, grouped to the east of Broad, and the negroes between Broad and the Schuylkill. In this region are located most of the slums of the city, though the peculiarities of the building plan permit them to exist in the rear of the best residential sections. West of the Schuylkill, Market Street continues to divide West Philadelphia into two distinct residential portions; for the northern the character is largely determined by the proximity of the main freight yards of the Pennsylvania Railroad, whose employees, together with employees from the downtown business district, constitute the bulk of its population. The southern is a more pretentious residence district, with many notable residences and with an academic air imparted to it by the presence of the University of Pennsylvania. Especially noted for their villas and gardens are the attractive suburbs of Germantown and Chestnut Hill; and in the general beauty of its numerous suburban sites Philadelphia is unsurpassed by any city of the world.

By its name Philadelphia suggests its distinctive title "The City of Brotherly Love;" its early history renders especially appropriate that of "the Quaker City;" but none more truly characterizes it than that of "The City of Homes." Of 323,783 buildings of all kinds (1903), 298,144 are dwelling houses, with an average of 4.5 persons per dwelling, and with 22 per cent. owned by the occupants. There are 800 church buildings, 474 schools, public and private, and 247 buildings used for charitable and benevolent purposes. In the older portions there are many survivals of the long blocks of red brick houses, with white marble steps and trimmings, that early gave Philadelphia the neat appearance for which it is still famous. In the newer portions red brick is still the principal building material, and the residences are commonly built in long blocks of houses of four or more similarly arranged rooms, each separated from its neighbors by a brick party-wall, and varying in size with the width of the street. On some of the larger streets the houses are built in pairs, instead of blocks, but the arrangement of the separate houses is the same. There is, however, a more welcome variety in styles of architecture than formerly, and various kinds of building stone, along many streets, are beginning to break the monotony of the customary brick, while in the better suburbs the residences are almost wholly of stone or wood. In general, Philadelphia, in its homes and parks, may be said to retain to a greater degree than any other large American city the finer qualities of its early town life and to combine with these the best features of modern industrial development.

Buildings. Adherence to an early architectural idea has made Philadelphia one of the last of large American cities to favor tall buildings. Very recently, however, a group of tall structures has sprung up in the vicinity of the 'Public Buildings,' as Philadelphians designate their City Hall. This immense structure, begun in the early 70's, and covering 4½ acres, accommodates all the municipal and county officers, and the State and county courts. It is a marble edifice, of modern French Renaissance style, 90 feet high, rising in corner pavilions to 161 feet, in central pavilions to 203 feet, and in the tower surmounted by a colossal statue of Penn (37 feet high and weighing 53,348 pounds) to a height of 547 feet 11½ inches. The building, inclosing a large central court, measures 486 feet 6 inches by 470 feet, and in it are 634 rooms, with a floor space of 14½ acres. In the tower are four great clock dials, each with a minute hand eleven feet long and weighing 225 pounds, and regulated by a vibration and temperature proof clock 143 feet below. The cost of the Public Buildings up to December 31, 1902, was $24,344,350, of which some $18,250,000 was for construction proper.

Among the important Federal buildings located within the city are the new United States Mint, on Spring Garden Street, one of the largest and most completely equipped in the world; the Post

Office Building, bounded by Market, Chestnut, Tenth and Ninth, occupying the site of the first President's Mansion and the subsequent home of the University of Pennsylvania; the Custom House, on Chestnut Street near the Delaware, modeled after the Parthenon, and erected in 1819-24 for the Second United States Bank; the Arsenal, below South Street near the Schuylkill; and at the southern end of Broad Street, the large League Island Navy Yard. Of the historic buildings the most important are the familiar Independence Hall and Carpenter's Hall on Chestnut Street, inseparably associated with the early Continental and Federal Congresses; the Betsy Ross House on Arch Street, where the first American flag was made; the Old Swedes (1700) and Old Christ (1727) churches of Revolutionary fame; and the first United States Mint, on Seventh Street below Market. The Pennsylvania Historical Society, one of the strongest organizations of its kind in the country, has an elegant building at Thirteenth and Locust streets.

Now that Philadelphia has adopted the modern steel frame building (with a careful regulation of height, however), its recent business structures will compare favorably in size and importance with those of any other American city. Among the leading office buildings may be mentioned the Land Title Annex (319 feet high); the pioneer Betz Building; the Real Estate Trust Building; the Arcade Building, and the Commonwealth Trust Building—all grouped around the City Hall; and the Real Estate Title and Trust Company Building, the Drexel Building, the Bullitt Building, and the Provident Building—notable structures of the financial area. In this vicinity, also, is the Philadelphia Contributionship 'Hand in Hand,' the oldest fire insurance company in America, of whose directorship Franklin was an early member. The Pennsylvania Railroad station, with a train shed over 700 feet long, and the Reading Terminal, a handsome railroad station, approached like that of the Pennsylvania Railroad by a viaduct, are notable railway terminals and office headquarters. Of newspaper buildings the most prominent are those of *The North American* (22 stories), *The Record*, and *The Public Ledger*. Of semi-public organizations the Stock Exchange is housed in the remodeled Merchants' Exchange Building; the Bourse Building is the home of the Board of Trade, the Trades League, and other trade organizations; and the Commercial Museum, supported by municipal, State, and Federal appropriations, and devoted to the encouragement of foreign commerce, especially with Spanish America, is located temporarily on Fourth Street, pending the erection of a permanent structure in West Philadelphia, on the site of the Exposition of 1899. Philadelphia has many important hotels, among the most elegant and commodious of which may be mentioned the Walton and the new Bellevue-Stratford, both on Broad Street near City Hall.

With structures representing interests that are not strictly utilitarian Philadelphia is well supplied. The Masonic and Odd Fellows' temples, on North Broad Street, rank with the best society structures on the continent. The Young Men's Christian Association Building on Fifteenth Street, that of the Young Women's Christian Association on Arch street, the Crozier Building of the Baptist Publication Society, the Witherspoon Building, with the publication rooms, general offices, and historical museum of the Presbyterian Church (North), represent in highest perfection the application of modern business methods to religious work. In addition to the historic churches already mentioned, the most important edifices are the Roman Catholic Cathedral, the Kenneth Israel Synagogue, and the Baptist Temple on North Broad Street, Holy Trinity (Protestant Episcopal) on Rittenhouse Square, the Arch Street (Methodist Episcopal), the First Presbyterian and the Tabernacle Presbyterian and the Friends' Meeting House on Arch Street—the Quaker Westminster of America. Of educational institutions the University of Pennsylvania, Drexel Institute, the new Boys' High School, Girard College with its early Grecian structures, and the Roman Catholic High School are architecturally of importance.

Parks. The system embraces about 4000 acres. Public interest has been aroused of late in the development also of parkways. William Penn expressed the desire to make Philadelphia a 'greene country towne;' and his surveyor Holme placed on the plan, near its four angles, rectangular open spaces, now Logan (northwest), Rittenhouse (southwest) Franklin (northeast), and Washington (southeast) squares, containing an aggregate of 28½ acres. These, together with Central Square, the site of the original waterworks, but now of City Hall, formed a cherished precedent. In 1903 there were under the care of the Bureau of City Property more than 50 small parks and plots containing over 600 acres. The largest was League Island Park (300 acres), contiguous to the League Island Navy Yard. In Independence Square the Declaration of Independence was read to the populace. Penn Treaty Square marks the site of the great elm under which, according to tradition, the founder made his famous compact with the Indians. In Logan Square was held in the summer of 1864 the great Sanitary Fair. Bartram's Garden (27 acres), on the banks of the Schuylkill, was the first botanical garden in the New World. Its noteworthy arboreal collection has been preserved.

The city's greatest pleasure ground is Fairmount Park, rich in natural beauties. The Schuylkill divides it into East Park, with over 633 acres, and West Park, with 1323 acres. Along the Wissahickon is the Wissahickon Valley extension of 1010 acres. The acquisition in 1812 of five acres on Morris's Hill, the original Fair Mount, for water-works and park purposes, led to the formation of the park. To this were added areas of woodland, and country seats, the Lansdowne estate of Governor John Penn, Eaglesfield, Sweet Briar, and Solitude; the Belmont home of Judge Peters of the Supreme Court, where Washington, Franklin, Jefferson, Lafayette, and others visited; Mount Pleasant, the residence of Benedict Arnold; George's Hill (83 acres), presented by Jesse and Rebecca George; Strawberry Mansion, Lemon Hill, Ormiston, and Edgely. The miniature Letitia House, built by William Penn for his discontented daughter, was transported from the city. The Zoölogical Gardens are maintained by private subscription, admission receipts, and municipal appropriations contingent upon the free admission of school children. The Centennial Exposition of 1876 brought many noteworthy structures into the park, the most important that remain being Horticultural Hall, with a fine exotic collection, and Memorial Hall,

INDEPENDENCE HALL

PHILADELPHIA

CITY HALL

where are exhibited the Wilstach Art Collection and the display of the Pennsylvania Museum and School of Industrial Art. A trolley line, below grade, eight miles long, extends to the chief points of attraction. A speedway, one mile in length, is being completed. The Schuylkill is frequently the scene of regattas, and there are handsome stone boat houses on its eastern bank.

Many fine monuments have been placed in the park. The Washington Monument by Siemering of Berlin is the most imposing. Funds for its erection were provided by the Society of the Cincinnati, the subscriptions, begun in 1819, aggregating $250,000 when the monument was unveiled in May, 1897. It stands at the Green Street entrance, the termination of the Park Boulevard. This thoroughfare, projected in 1903, is to be 160 feet wide from City Hall to Logan Square, and thence 300 feet wide to the park. In the same year was authorized the construction of the Torresdale Boulevard, 300 feet wide and 15 miles long, from North Broad Street to Torresdale. Of note are the statues of Lincoln, Garfield, Grant, Meade, Humboldt, Schiller, Goethe, Columbus, Joan of Arc, Witherspoon, and Father Mathew; and the Catholic Total Abstinence Union Fountain, and the Smith Memorial Arch. Grant's Cabin, occupied as headquarters at City Point, is here preserved. In the city proper are comparatively few works of art, the most important being statues of Washington in front of Independence Hall, of Franklin on the post-office pavement, and of McClellan and Reynolds on City Hall Plaza.

The Wissahickon Valley, a deep wooded ravine, which has been left almost in its original wild state, is of interest for its memories and legends of Indian braves and mystic German monks who made it their retreat. The first paper mill in America was erected on its banks in 1690. In Fairmount Park there are 20 small streams, several lakes, and more than 150 springs; over 66 miles of drives, 10 of bridle paths, and 40 of smaller roads. The boundary line is 30 miles long. The entire cost approximates $7,000,000, and $3,500,000 has been expended in permanent improvements.

The Laurel Hill cemeteries are contiguous to the park. In the city are numerous burial places, many of historic associations.

Educational Institutions and Libraries. At the close of 1902 there were in the city six higher schools, including a high school for boys, conferring degrees of A.B. and B.S., and a school of pedagogy; a high school, a commercial high school, and a normal school for girls; and two manual training schools. There were also one school of industrial art, one elementary manual training school, one observation and practice school, five special schools for backward children and truants (under the compulsory education law), twelve cooking schools, and grammar, primary, and kindergarten schools, making the total of city institutions 420, with 229 male and 3537 female teachers, and an attendance of 158,473, of which 5800 were in the higher schools. The general course of study falls under no classification, but is the result of development. Foreign languages are taught only in the higher schools. There is some special and experimental manual training for seventh and eighth grade boys, and cooking and sewing instruction for sixth, seventh, and eighth grade girls. Through private bequest and municipal legislation there are available 358 free scholarships in the University of Pennsylvania, Bryn Mawr, Lehigh University, and various medical, art, and scientific colleges. Night and summer vacation schools are conducted.

At the head of the higher educational institutions is the University of Pennsylvania (q.v.). Philadelphia is a centre of medical education, its prominent medical colleges being that of the University of Pennsylvania, Jefferson, Hahnemann, Medico-Chirurgical, Polyclinic, and Woman's (founded in 1850), the first chartered medical college for women in the world to confer the degree of M.D. The Pennsylvania and Philadelphia dental colleges (the oldest and the best of their kind) and the Philadelphia College of Pharmacy are largely attended. The art schools of the Pennsylvania Academy also are the oldest in the country. The School of Industrial Art and the School of Design for Women are well known. Bryn Mawr College (q.v.), near Philadelphia, is one of the foremost women's institutions of the United States. The Drexel Institute, founded and endowed with $2,000,000 by A. J. Drexel, offers at a small cost courses in art, sciences, and industrial training. Other leading institutions are the Franklin and Spring Garden Institutes, Temple College, Episcopal Academy, the seminaries of the Protestant Episcopal, Lutheran, and Roman Catholic churches, La Salle and Saint Joseph's Colleges, and the Roman Catholic High School, the Methodist Episcopal Collegiate Institute for Girls, numerous schools of the Society of Friends, including the William Penn Charter (1701), the first chartered school in the country, the Cheltenham Military Academy, and the Germantown Academy (1760). The Williamson Free School of Mechanical Trades, established under a bequest of $2,500,000 by the late I. V. Williamson, offers complete trade courses and supports students free of cost. Philadelphia is noted for its associations and institutions for the promotion and diffusion of science and learning, and the encouragement of art. Among these are the Philadelphia Academy of Natural Sciences (q.v.), the Franklin Institute (q.v.), the American Philosophical Society, the American Academy of Political and Social Science, the Historical Society of Pennsylvania, the Zoölogical Society, the Numismatic and Antiquarian Society, the Pennsylvania Academy of Fine Arts, and the Wagner Institute.

The Free Library, now in temporary quarters, founded in 1891, on bequests of George S. Pepper and others, is maintained by appropriations made by City Councils. In the central and 14 branch libraries are over 250,000 volumes. A gift by Andrew Carnegie of $50,000 for each of thirty additional branches with halls for public gatherings (conditional upon their maintenance by the city), and an appropriation of $1,000,000 for a permanent central building, provided by a loan approved by popular vote, are awaiting expenditure. The Library Company's collection, begun in 1731 by Benjamin Franklin and his associates of the 'Junto,' formed the first subscription library in America. Its 200,000 volumes include many of extreme rarity. The Ridgway Branch, an excellent example of pure Greek architecture, contains one of the most valuable reference lists in the United States. Other important libraries

of the 100 in the city are the Mercantile (1821), general circulation and reference; Carpenters' Company (1756), architecture and building; Friends' (1742); American Philosophical Society (1743); Academy of Natural Sciences; Franklin Institute, scientific; Hurst, law; College of Physicians; University of Pennsylvania, Apprentices', Pennsylvania, Presbyterian, and Baptist Historical societies; Drexel Institute; and the H. Josephine Widener Branch of the Free Library, with a valuable collection of reference works.

Hospitals and Other Institutions. The municipal charities are the hospitals for the Indigent and for the Insane, General Hospital, and the Municipal Hospital (contagious diseases). The Pennsylvania Hospital, founded in 1751, through the efforts of Franklin, and maintained entirely by private subscription, is the oldest institution of the kind in America. The religious denominations maintain institutions, among them being Saint Agnes', Saint Mary's, and Saint Joseph's hospitals (Roman Catholic); Episcopal, Methodist, Presbyterian, Jewish, Saint Luke's (Baptist), and German (Lutheran) hospitals. Large hospitals are connected with the University, and Jefferson, Medico-Chirurgical, Polyclinic, Hahnemann, and Woman's Medical colleges. Other important charities are the Rush and Phipps hospitals for consumptives, the Gynecean, Orthopaedic, Wills Eye, and Maternity hospitals. There are more than 100 dispensaries, homes, asylums, orphanages, etc. The College Settlement, Society for Organizing Charity, Working Women's Guilds, Flower, Fruit, and Ice Mission, various children's aid, protection, and country week associations do good work. The city maintains numerous public baths, which were patronized in 1902 by 4,153,000 persons.

Girard College, founded by Stephen Girard, who at his death in 1830 gave $2,000,000 for construction and the greater portion of his $5,000,000 estate for endowment, supports and educates annually over 1600 orphans. The residuary fund now amounts to $16,500,000. The Citizens' Permanent Relief Committee has relieved thousands of distressed in all parts of the world, over $5,000,000 having been distributed since 1879. The Mayor is president. The penal institutions are the Eastern State Penitentiary, the House of Refuge (boys and girls), the House of Correction (adults), and Moyamensing and Holmesburg County prisons.

Theatres and Clubs. The drama in America began in Philadelphia, a company being organized in 1749. The first permanent playhouse in the city was built in 1766; a portion of its walls still stands. The Walnut Street Theatre is the oldest in the country. At Locust and Eighth streets stands the Musical Fund Hall, where Malibran, Jenny Lind, and Ole Bull appeared. Other important playhouses are Keith's New Theatre, the Garrick, the South Broad, the Chestnut Street, the Grand and Chestnut Street opera houses, and the Auditorium. The Academy of Music, with a capacity of 4000, is used for large public gatherings.

Leading clubs are the Union League, with a handsome brownstone building; Philadelphia, Manufacturers', Mercantile, Rittenhouse, Markham, Columbia, University, Penn, Art, installed in a beautiful Renaissance [illegible] of Pompeian brick and Indiana limestone; Sketch, Lawyers' Clover, Five o'Clock, Maennerchor, Franklin, Country, Pen and Pencil, Philadelphia Yacht, and the New Century and Acorn (women's).

Commerce and Manufactures. The industrial development of Philadelphia has been greatly aided by the favorable location of the city for commerce, and especially by its proximity to raw materials. The city has the advantage of superior railroad facilities. The great Pennsylvania Railroad system, with 10,484 miles of owned and leased lines, and the Philadelphia and Reading Railway, with $140,000,000 capital and 1457 miles of track, terminate and have home offices near the City Hall. The Pennsylvania lines give Philadelphia more direct communication with the productive Middle West than is enjoyed by any other Atlantic port. The general offices of the Lehigh Valley Railroad are in the city. The Baltimore and Ohio enters where Chestnut Street crosses the Schuylkill. The tracks of the Pennsylvania are nearly all elevated or below grade, the Baltimore and Ohio below, and the Reading partly above, partly below, but mainly at grade. The Delaware River admits of the entrance of ocean vessels, and is navigable the entire length of the city's frontage, 18 miles. Work is now in progress to deepen the river to 30 feet. The Schuylkill River is navigable eight miles for vessels of light draught and is being dredged to a depth of 22 feet. The general export and import interests, including the Port Richmond coal wharves, are located mainly on the Delaware. Eleven transatlantic lines enter the port.

Early in the nineteenth century Philadelphia was first among United States ports in foreign commerce, but its relative importance declined, until in 1901 it ranked fourth. The imports for that year were valued at $48,043,443, and the exports at $79,354,025. In 1901, 158 sailing vessels, with an aggregate of 115,779 tons, and 950 steam vessels, of 1,807,623 tons, entered the port. The pipe lines of the Standard Oil Company from the wells in the northwest section of the State terminate at Point Breeze, on the Schuylkill, and oil is one of the largest and most valuable shipments of the port. In 1901 the exports of illuminating mineral oil amounted to 207,111,311 gallons, valued at $12,323,961. The exports of corn for the same year amounted to $12,633,467, one-seventh of the total for the country. Wheat and flour are also exported extensively. In 1901, 37,833 head of cattle were shipped, and there were also considerable exports of meat and meat products. Coal and copper are other important exports. The largest import is sugar, amounting in 1901 to a value of over $15,500,000. Imports of unmanufactured silk were valued at over $8,000,000. Among other leading imports are goat skins, fabrics, bananas, etc.

Philadelphia is a great manufacturing centre, ranking third in the United States in value of products. Of 15 selected industries in the census year 1900, it was first in one (leather), second in two (cigars and cigarettes, and women's factory clothing), and third in six. The value of the total output was $732,137,957. This was nearly double the corresponding figure for 1880, but the greater part of the increase was made in the decade 1880-90. The manufacture of foundry and machine shop products is most important, amounting in 1900 to $38,372,971. In this industry Philadel-

phia has a special advantage, owing to its proximity to abundant resources of coal and iron. It is noted particularly for the manufacture of locomotives, the Baldwin Locomotive Works, on North Broad Street, having a yearly capacity of 1500. For years Philadelphia has been the foremost shipbuilding centre in the country. Many warships of the United States and also a number for foreign governments have been built at the Cramp shipyard, which occupies some 52 acres in the Port Richmond section. These two establishments are not only the leading ones of Philadelphia, but each excels, in its own line, for the country at large. In the total manufacture of textiles also the city ranks first (though not for any one branch), the value of the principal textiles produced in 1900 being as follows: Woolen goods, $18,340,012; worsted goods, $16,242,250; cotton goods, $15,723,654; hosiery and knit goods, $13,040,905; silk and silk goods, $4,531,794. The output of the sugar and molasses refining industry was valued at over $36,000,000; the output of clothing, $28,000,000; of carpets and rugs, nearly $22,000,000; of leather, nearly $20,000,000; and of liquors, over $12,000,000.

Government. The executive branch of the government is of a dual nature, consisting of county and municipal departments. The municipal form of government is provided for by the Bullitt Bill, act of June 1, 1885, amended April, 1903, the basic elements of which are concentration of authority in the mayor and the distinction between the executive and legislative functions. The executive departments are: Public Safety, which includes bureaus of police, fire, electricity, corrections, boiler inspection, building inspection, and city property; Public Works, which includes bureaus of water, highways, gas, lighting, street cleaning, surveys, ice boats, and filtration (temporary); Law, Education, Public Health and Charities, Receiver of Taxes, City Comptroller, and City Treasurer (ex-officio County Treasurer), and Supplies. The mayor, who is elected every four years and is ineligible for succession, appoints directors of the Departments of Public Works, Safety, Health, and Supplies, subject to confirmation by Select Council. Directors appoint chiefs of bureaus and other employees under civil service requirements. The receiver of taxes, city treasurer, city comptroller, and city solicitor are elected by popular suffrage. The Department of Education consists of 42 comptrollers, appointed by the judges of the Courts of Common Pleas. The Sinking Fund Commission consists of the mayor, city comptroller, and one member elected by Councils. The commissioners of Fairmount Park and members of the Board of Revision of Taxes, and the Board of City Trusts, in charge of Girard College and Estate and minor trusts, are also appointed by the courts. Sixteen port wardens are elected by the Councils. The county officials are commissioners in charge of elections, etc., treasurer, recorder of deeds, register of wills, clerk of the Court of Quarter Sessions, coroner, sheriff, and district attorney. The legislative function is exercised by Select and Common Councils, the former consisting of one member from each of 42 wards, the latter of one member for every 4000 voters. Select Councilmen serve three years, and Common Councilmen, two, without pay. The veto power is vested in the mayor, a three-fifths vote enacting over it. The judiciary consists of police magistrates (limited civil and preliminary criminal actions); judges of the Courts of Common Pleas (civil), who are also judges of the Courts of Quarter Sessions (criminal); and the judges of the Orphans' Court (estates). The Superior and Supreme Courts of Pennsylvania and the United States District and United States Circuit Courts sit in the city.

The city has leased its gas-works for a maximum period of 30 years, expiring December 31, 1927. Electric lighting is supplied by a private corporation. The water-works are under municipal ownership. A system of slow sand filtration is being installed, and in August, 1903, when upward of $17,000,000 was involved in contracts, it was over half finished and in partial operation. The complete works, with a daily capacity of 300,000,000 gallons, are estimated to cost $26,000,000.

Finances. The city's receipts for 1902 were $33,520,729. The important items were: taxes, $16,793,680; gas, $486,491; State appropriation (1901-02) for schools and teachers' annuities, $316,000; loans negotiated, $6,915,000; personal property tax, $1,249,332; permits, fees, etc., $7,400,000, including water rents, $3,422,000, liquor licenses, $1,766,000, and premiums on loans, $581,030; interest, $365,000. The expenditures were $34,605,948; the largest item was $25,904,693 for municipal departments and bureaus; of this amount schools received $4,186,000; police, $3,565,000; fire, $1,124,000; water, $6,511,000; highways, $2,109,000; street cleaning, $1,238,000. Other large disbursements were: interest on funded debt, $1,404,036; several sinking funds, $1,727,787; loans redeemed, $680,000; mandamuses, $1,456,105. The general cash balance on January 1, 1903, was $17,166,865. The gross debt at the same date was $59,361,845; the city loans held by the sinking fund amounted to $6,645,300, leaving a net city debt of $52,716,545; the total assets were $29,132,473, not including the real estate owned by the city, valued at $64,520,994. The assessed real estate valuation, as estimated in August, 1903, for 1904, was $1,160,392,710. Under the law the debt is limited to 7 per cent. All permanent loans after the 2 per cent. point has been exceeded must be authorized by a vote of the people.

Population. The population in 1900 was 1,293,697, Philadelphia ranking third among American cities. Since 1854 no territory has been added to the municipal limits. The percentage of increase from 1880 to 1890 was 23.58, and from 1890 to 1900, 23.57. Fifty-four and seven tenths per cent. of the white population is of foreign parentage, but native whites of foreign birth comprise 32 per cent. of the entire population. The negroes numbered 28,940 in 1900; Chinese, Japanese, and Indians, 1277. The largest classes of European descent are German, Irish, English, and Italian. French, Greeks, Armenians, Russians, Bohemians, and Poles are present in much lesser numbers. Though some tendency to congregate is shown, there are few well defined foreign colonies. In 1800 the population of Philadelphia was 28,522; in 1820, 63,802; in 1840, 93,665; in 1860, 563,529; in 1880, 847,170; in 1890, 1,046,964.

History. The first settlement (called Wicaco) within the present limits of Philadelphia was made in 1636 by a company of Swedes sent out by the Government of Queen Chris-

tin. On October 7, 1681, Captain William Markham, Deputy Governor for William Penn, arrived with a small company, and started an English settlement here, which in July of the following year was laid out and called Philadelphia, 'the city of brotherly love.' In 1683 a company of Germans, invited hither by Penn, arrived and settled at Germantown, within the present city limits. In 1684, immigration having been rapid from the start, there were 300 houses and more than 2500 inhabitants. The majority of the early settlers were Friends, and their influence, combined with that of the Germans, predominated for many years and greatly affected the course of Pennsylvania's history. Penn returned to England in 1684, and did not revisit the city until 1699, when he found a population of 4500, and 700 houses. He chartered the city in 1701, and thereafter frequent controversies arose between the people and the Penn family over proprietary privileges, especially as regards taxation of the Penn lands. The first English school was opened in 1683. Franklin's *Pennsylvania Gazette* began publication in 1729 and the *Pennsylvania Journal and Weekly Advertiser* was started in 1742. In 1741 the city, then having 1621 taxable citizens, was divided into ten wards. In 1723 Benjamin Franklin, who, next to Penn, exerted the greatest influence in the history of the city, came to Philadelphia. In 1747, during King George's war with the French and Indians, the publication of his *Plain Truth* roused a spirit of military enthusiasm, a force of 10,000 was raised in Pennsylvania, and a battery was erected below the city, on the site of the present United States Navy Yard. In 1751 the first line of packets to New York was established, followed in 1756 by a stage line. Under Franklin's influence, in 1747 the merchants of Philadelphia sent a ship to discover the Northwest Passage. In 1755 a militia bill was passed, and Franklin became colonel of the city regiment.

From 1763 to 1774 Philadelphia was prominent in resisting British aggression, though the Loyalist party was strong, and most of the Friends opposed warfare; and here most of the important official events of the Revolution took place. In 1773 (October 17), during the excitement over the expected arrival of the tea ships, the people met in mass meeting and passed resolutions which, on November 5th, were readopted at Boston. The first Continental Congress met in Carpenter's Hall, September 5, 1774; the second met May 10, 1775, in the State House; and there, on June 15th, Washington was appointed commander-in-chief of the Continental army. In 1776 Congress met for the third time in the State House, and there, on July 4th, the Declaration of Independence was adopted. Philadelphia was held by the British from September 27, 1777, to June 18, 1778, and during this period, while the American army was at Valley Forge, was the scene of much gayety. On May 18, 1778, the famous entertainment called the Mischianza (q.v.) was given in honor of General Howe, who was about to depart for Europe. On October 4, 1777, the battle of Germantown (q.v.) was fought. On May 2, 1787, delegates from the different States assembled here, and, after almost four months of debate behind closed doors, adopted a Constitution for the United States, September 17th. On March 11, 1789, the city received a new charter from the legislature. Epidemics of yellow fever in 1793 and 1798 caused great loss of life, at least 4000 dying in the former year and almost 5000 out of the 30,000 who remained in the city in the latter.

During the latter part of the eighteenth century and the early part of the nineteenth Philadelphia was the most important city in America. The historian McMaster says of it in 1784: "The city was then the greatest in the country. No other could boast of so many streets, so many houses, so many people, so much renown;" and Liancourt describes it in 1800 as "not only the finest city in the United States, but . . . one of the most beautiful cities of the world." Philadelphia was the capital of Pennsylvania from 1683 until 1799, the seat of the Federal Government from 1790 to 1800, and the monetary centre of the country until 1836. (See BANK, BANKING.) For many years, also, it was the intellectual and literary centre of the country. Here were published the first newspaper in the middle colonies, *American Weekly Mercury* (1719); the first secular magazine in North America, *Ein geistliches Magazin* (1764); the first daily newspaper in the United States, the *Pennsylvania Packet* (1784); the first American edition of the Bible in German (1743), and in English (1781), and the first religious weekly, *Religious Remembrancer* (1813). The most popular of the early American magazines—the *Port Folio* and the *Analectic*—were also published here.

Philadelphia took the lead in the early anti-slavery movement, the first formal protest against slavery in this country being made by four Germans of Germantown in 1688, the first Abolition convention being held here January 1, 1794, on the invitation of the Pennsylvania Abolition Society, and the American Anti-Slavery Society being founded here, under the leadership of Garrison, in 1833. In 1812 the water-works at Fairmount were begun and were finished in 1815. In 1832 nearly 1000 deaths resulted from Asiatic cholera. In May, 1838, an anti-Abolitionist mob destroyed Pennsylvania Hall, in which an Abolitionist meeting had been just held. In 1844 occurred the anti-Catholic riots, arising from the demand of the Catholics to be permitted to use the Douai instead of the King James Bible in the public schools. The anti-Catholics, or 'Native Americans,' burned Saint Michael's and Saint Augustine's churches, and caused much loss of life before they were put down by the militia. Gas was introduced in 1836, and the first telegraph line was established in April, 1846. On February 2, 1854, a consolidation act was passed by the Legislature, extending the city limits to the county boundaries, and uniting under one municipal government all the outlying districts, known as Southwark, Northern Liberties, Kensington, Spring Garden, Moyamensing, Penn, Richmond, West Philadelphia, and Belmont; also the boroughs of Germantown, Manayunk, and other townships. Philadelphia took an active part in the Civil War, and raised more than $1,000,000 by a sanitary fair in 1864. The centenary of American independence was celebrated in 1876 by the Centennial Exposition; the bi-centennial of the landing of William Penn in 1882; and the centennial of the signing of the Constitution in 1887.

cott, *History of Philadelphia, 1609-1884* (ib., 1884); Allinson and Penrose, *Philadelphia, 1681-1887* (ib., 1887); Trades League, *The Book of Philadelphia*, 1894 (ib., 1894); Repplier, *Philadelphia, the Place and the People* (New York, 1895); Young, *Memorial History* (ib., 1895); Fisher, *The Making of Pennsylvania* (Philadelphia, 1896); id., *Chapters in Pennsylvania, Colony and Commonwealth* (ib., 1897); Rhoades, *The Story of Philadelphia* (New York, 1900); King, *Philadelphia and Notable Philadelphians* (ib., 1902).

PHILADELPHIA ACADEMY OF NATURAL SCIENCES. An association founded in 1812 for the purpose of furthering the study of the natural sciences and encouraging original investigation in the various fields of physical research. It is the oldest organization in the United States devoted to the encouragement of natural science. Its museum is especially rich in ornithological specimens and fossils, while its collection of shells is the finest in the world. The Jessup foundation provides gratuitous training for a number of young investigators. The society has published a *Journal* since 1817 and its *Proceedings* since 1841.

PHIL'ADELPH'US (Neo-Lat., from Gk. *φιλάδελφον, philadelphon*, sort of flowering shrub, perhaps jasmine; named in honor of Ptolemy Philadelphus, King of Egypt). A genus of shrubs of the natural order Saxifragaceæ. Several species are natives of the southern Atlantic and Pacific States and Japan. *Philadelphus inodorus* grows in the mountains from Virginia southward. *Philadelphus grandiflorus* grows in lower ground in the same region. *Philadelphus hirsutus* grows in Tennessee and North Carolina. *Philadelphus Gordonianus* and *Philadelphus Lewisii* are natives of the Pacific Coast States. The most common and best representative of the genus, however, is *Philadelphus coronarius*, the common mock orange or syringa, much cultivated in gardens. Its native country is not known, but it was probably brought from Japan to Southern Europe, where it appears to be indigenous. It has erect branches, oblong ovate leaves, which when crushed have very much the odor and taste of cucumbers. Its cream-colored flowers, borne in large clusters, are well known for their exceeding fragrance.

PHI'LÆ (Lat., from Gk. *Φιλαί*, Coptic *Pilâkĕh*, the corner, extremity, i.e. of Egypt). A celebrated island in the Nile, just above the First Cataract, in latitude 24° 1′ N. It is a small granite rock, about 1000 feet long by 500 feet broad, and is covered with ancient buildings of great architectural beauty and interest. By the Arabs it is called *Gezîret Anas el-Wogûd*, 'The island of Anas el-Wogûd,' from the name of the hero of a tale in the *Thousand and One Nights*, the scene of which is laid here. Philæ is not mentioned in the Egyptian inscriptions before the time of Nectanebo II., who constructed the oldest of the buildings that now remain, though it is reasonably certain that a temple existed there in earlier times. The island was especially devoted to the worship of the goddess Isis, but Osiris, Hathor, Khnum, Satet, and other divinities were also worshiped there. In later times, when the cult of Isis had spread through the Greek and Roman world, many pilgrims of foreign nationality visited the shrine of the goddess at Philæ, and her worship was maintained there long after heathenism had been banished from other parts of Egypt. The great temple of Isis was built by Ptolemy Philadelphus and his successor, Euergetes I., but additions and embellishments were made by other Ptolemies and by several of the Roman emperors. The approach to the temple is formed by the dromos, a long open space, flanked on its eastern and western sides by colonnaded walks. At the southern end is the hall of Nectanebo II., built about B.C. 350, and near it to the right is the ruined temple of the Nubian deity Arnuphis (Ar-hes-noter). Starting from this temple, the eastern colonnade runs northward to the small temple of Imhotep (Asklepios), and terminates near a gate built by Ptolemy Philadelphus and adorned with reliefs by that monarch and by the Emperor Tiberius. The western colonnade is pierced by a number of windows which give a fine view over the river. It runs along a fine stone quay of ancient construction. At the northern end of the dromos stands the great pylon of Nectanebo II., leading into the outer court, on the eastern side of which are a number of chambers, built for the use of the priests, while on the western side is the birth-house, commemorating the birth of Horus. Among the reliefs and inscriptions upon the walls of the latter building is a copy in hieroglyphic and demotic of the text of the Rosetta stone (q.v.). At the upper end of the outer court is a second pylon, which gives entrance to the inner court leading to a columned hall, and from this, through a succession of smaller halls and chambers, lies the way to the sanctuary of the goddess Isis and her son Harpocrates (q.v.). In an upper story is a room decorated with scenes from the myth of Osiris (q.v.). The temple is decorated throughout with sculptures and reliefs which are well preserved and are richly colored. West of the temple of Isis, near the river, are a gate built by the Emperor Hadrian and the temple of Harendotes (Egyptian *Har-ne-tawy*, 'Horus the avenger of his father'). On the eastern side of the island is the small temple of Hathor built by Ptolemy Philometor and Euergetes II., and near it, close to the river bank, is a beautiful pavilion resting upon light and graceful columns and richly adorned with reliefs. On the northern end of the island, among the ruins of the ancient city of Philæ, are the remains of the old Roman city gate, of the temple of Augustus, and of a Coptic church. It was expected (1903) that the great dam at Assuan would so raise the level of the Nile at Philæ as to submerge the island. See Plate accompanying article EGYPTIAN ART.

PHILANDER. A Dutch knight in Ariosto's *Orlando Furioso*, who made love to Gabrina, the wife of his host. His name is used as the synonym of a male coquette in various plays, and is the origin of the verb to philander.

PHILANTHROPY (Lat. *philanthropia*, from Gk. *φιλανθρωπία*, love of humanity, from *φιλάνθρω-*

πος, *philanthrōpos*, loving humanity, from φιλεῖν, *philein*, to love + ἄνθρωπος, *anthrōpos*, man). In German educational history, a term applied to the theories of a group of men who based their educational theories upon Rousseau. At the head of these was Basedow, who founded an institution, the Philanthropinum, at Dessau in 1774. The only survival of the movement is Salzmann's institution at Schnepfenthal in Gotha, founded in 1784. See BASEDOW.

PHILARET, fĭl'ȧ-rĕt (VASILI FEODOROVITCH DROSDOFF) (1783-1867). Metropolitan of Moscow. He was born at Kolomna; became a priest in 1808 and in 1812 was made rector of the Theological Academy of Saint Petersburg. In 1817 he became Bishop of Revel, in 1819 Archbishop of Tver and a member of the Holy Synod. In 1820 he was transferred to Yaroslav and in 1821 to Moscow. He was appointed Metropolitan of Moscow in 1825. He was noted for learning and eloquence, and drew up the manifesto which led to the abolition of serfdom. He prepared a longer and a shorter catechism, both of which were adopted and promulgated by the Holy Synod in 1839, and the former is considered the most authoritative doctrinal standard of the Graeco-Russian Church. Both catechisms have been translated into English by Blackmore in *The Doctrine of the Russian Church* (London, 1845); Blackmore's translation of the longer catechism is reprinted in Schaff, *The Creeds of Christendom*, vol. ii., pp. 445-542. There has also been published a volume of Philaret's *Select Sermons* in English translation (London, 1873), with brief biography. He began a translation of the New Testament into Russian, which was completed after his death.

PHILASTER, OR, LOVE LIES A-BLEEDING. A tragedy by Beaumont with some assistance from Fletcher. G. C. Macauley considers it the work of Beaumont alone. It was printed probably in 1608, and printed in 1620. Several versions were produced, one as late as 1764.

PHIL'ATEL'IC ASSOCIATION (from Gk. φίλος, *philos*, loving, from φιλεῖν, *philein*, to love + ἀτελής, *atelēs*, free of tax, prepaid, from α-, *a-*, not + τέλος, *telos*, tax, duty), AMERICAN. A national society of postage stamp collectors, founded in 1885, meeting annually in such cities as may be selected, and having local branch societies in New York, Chicago, Pittsburg, and Saint Paul. It has a membership of nearly six hundred, and its objects are to bring together those interested in philately, and to study that subject with the help of exhibitions of collections.

PHILATELIC SOCIETY OF LONDON. An English association of collectors of postage stamps, founded in London in 1869, the first of its kind. Its objects are the study of postage stamps, their history and manufacture, the detection of forgeries, the exhibition of stamps, and the publication of works on these subjects. The membership includes many collectors in the English colonies and on the Continent. The society has conducted two international philatelic exhibitions. It has also published expensive volumes on the stamps of Great Britain, of the British colonies, of India and Ceylon, and of Africa, and issues its proceedings in the *Monthly Journal*.

PHILAT'ELY. See POSTAGE STAMPS.

PHIL'BRICK, JOHN DUDLEY (1818-86). An American educator, born in Deerfield, N. H. He graduated at Dartmouth in 1842 and afterwards taught in Boston for ten years. In 1853 he became principal of the Connecticut Normal School, and in 1855 superintendent of schools in that State. From 1857 to 1874 and again from 1876 to 1878 he was superintendent of the Boston public schools. He was sent to the Vienna Exposition of 1873 as educational commissioner from Massachusetts, and acted as a member of the international jury. After his return he became president of the National Teachers' Association and was officer of many educational societies. He prepared a valuable report on the *City School Systems in the United States* (published by the United States Bureau of Education in 1885) and edited the Connecticut *Common School Journal*, and the *Massachusetts Teacher*.

PHILEL'PHUS. The Latinized form of the name of the Italian humanist Francesco Filelfo (q.v.).

PHILE'MON (Lat., from Gk. Φιλήμων) (c.361-263 B.C.). A Greek comic poet. He was a native of Soli, in Cilicia, or of Syracuse, in Sicily. He resided chiefly in Athens, but for a time also in Alexandria at the Court of Ptolemy Philadelphus. He and Menander were the two representative poets of the Attic New Comedy. Philemon gained more prizes than Menander, perhaps through bribery of the judges. Posterity, however, reversed the decision, and Menander and Homer were the two favorite poets of later Greece. Of the 97 comedies which Philemon left, 57 are known to us from titles and fragments, while two at least, the Ἔμπορος and Θησαυρός, are preserved in Plautus's adaptations, the *Mercator* and *Trinummus;* and it is also probable that Plautus's *Mostellaria* follows Philemon's Φάσμα. The fragments are published by Koch, *Comicorum Atticorum Fragmenta*, vol. ii. (Leipzig, 1886).

PHILEMON. A dear friend of the Apostle Paul, to whom he wrote the letter which is now preserved in the New Testament under Philemon's name. From this letter it appears that he was a rich man who probably lived at Colossæ, owned slaves, was noted for his hospitality, and had become a Christian under Paul's influence. There are legendary accounts of Philemon's later accession to the Bishopric of Colossæ and of his martyrdom there under the Emperor Nero.

PHILEMON, EPISTLE TO. One of the Epistles of the New Testament and the only letter of Paul written to an individual on a purely private matter which has been preserved. In it Paul appeals to his friend Philemon in behalf of Onesimus, a fugitive slave, who, under the influence of Paul, had become a convert to the Christian faith. This fugitive Paul sends back to his master with a letter praying for the culprit's pardon and even hinting at emancipation. The letter was, almost without doubt, written from Rome, some time after Paul's arrival there in the spring of A.D. 59. The most significant value of the letter is its bearing upon the question of human slavery. The practice is not condemned, but the new doctrine of the brotherhood of man is emphasized as in the Colossian and Ephesian letters, written at the same time. Consult: Ellicott, *Philippians, Colossians, and Philemon* (Andover, 1865); Lightfoot, *Colossians and Philemon*

(1876); Soden in *Hand-Commentar zum Neuen Testament*, vol. iii. (Freiburg, 1893); Moule, *Colossians and Philemon* (*Cambridge Bible for Schools and Colleges*, Cambridge, 1894); Vincent, *Philippians and Philemon* (*International Critical Commentary*, New York, 1897); Maclaren, *Colossians and Philemon* (*Expositor's Bible*, New York, 1903).

PHILEMON AND BAU'CIS. According to a myth related by Ovid in his *Metamorphoses*, a pair of poor Phrygian peasants. Jupiter and Mercury, wandering through Phrygia in human form, were hospitably entertained by them, when all the neighborhood had turned the wanderers from their doors. On going away the gods took them with them to a neighboring mountain, whence they saw their village covered with a flood, but their own cottage changed into a splendid temple. Jupiter permitted them to make any request they chose, but they only asked to be servants of his temple and to die at the same time. Therefore in their extreme old age the gods transformed Philemon into an oak, Baucis into a linden, which long stood in front of the temple, and were honored by the people. The story, which has been much elaborated by Ovid, contains two elements common in popular tales: the rescue from a flood by divine interposition and the reward for hospitality to supernatural visitors in disguise. The vitality of the legend in Phrygia seems emphasized by the experience of Paul and Barnabas at Lystra (Acts xiv.).

PHILE'TAS (Lat., from Gk. Φιλήτας) OF COS. A Greek grammarian and poet who lived about the close of the fourth century B.C., tutor to Ptolemy II. Philadelphus of Alexandria. His poems, which were chiefly elegies devoted to the praises of his mistress, Battis, were ranked next to those of Callimachus by the Alexandrian critics, and were imitated by Propertius. He wrote also epics and grammatical treatises. The scanty fragments that remain have been published by Bach (1829). Consult Weber, *Elegischen Dichtern des Hellenen* (Frankfurt, 1826).

PHILHARMONIC SOCIETIES (from Gk. φιλεῖν, *philein*, to love + ἁρμονία, *harmonia*, harmony). Organizations formed for the cultivation of orchestral music. The four most important are those of London, New York, Vienna, and Berlin.

LONDON. This is the oldest association of orchestral performers in England. In 1813 a number of music-lovers founded the Philharmonic Society and the first concert was given March 8th of that year. According to the constitution only concerted pieces were to be performed; all solo and concertos were excluded. But when a little later some of the members formed quartets the society ceased to perform chamber-music at its concerts and restricted itself to instrumental works for orchestra. In 1820 the term *conductor* (q.v.) appears for the first time upon the programmes, and it designated the person at the piano. After 1821 the conductor stood before the orchestra and directed by means of a baton. Since 1869 the organization has published analytical programmes for its concerts, at which the most eminent instrumental and vocal artists of their time have appeared.

NEW YORK. The Philharmonic is the oldest permanent orchestral association in New York. It was founded in 1842, the first concert taking place December 7th of that year. From the beginning it consisted of professional musicians only. As an educational factor the Philharmonic Society has been of greater importance in the musical life of America than any other organization, with the possible exception of the Boston Handel and Haydn Society. (See CHORAL SOCIETIES.) Up to 1865 various members of the orchestra acted as conductors. Beginning with that year a conductor for the season was chosen, the first being Carl Bergmann, who directed the concerts until 1876. After Dr. Damrosch had been conductor for one season, Theodore Thomas held the post from 1877 to 1890. This eminent director was succeeded by Anton Seidl. From 1898 to 1902 Emil Paur was conductor, and this period was marked by the production of an unusual number of new works, especially of the Neo-German school. In 1902 Walter Damrosch was conductor. The orchestra numbers over one hundred performers. Eight concerts take place on Saturday nights, each being preceded on Friday afternoons by a public rehearsal, which, in reality, is a regular concert, having its own list of subscribers.

VIENNA. The society, known as *Philharmonische Gesellschaft*, was founded in 1842 by Otto Nicolai, at that time conductor at the Imperial Opera. As the *Gesellschaft der Musikfreunde* (q.v.) was fast degenerating, there was a positive need of an organization that would give artistic performances. The first concert of the new society took place November 27, 1842, and the venture immediately met with great favor and financial success. The programmes consisted generally of two symphonies with smaller works. Instrumental solos, however, were not permitted. When Nicolai accepted a position in Berlin in 1847 the *Philharmonische Gesellschaft* almost came to an end. In fact, no concerts were given from 1850 to 1854. Then Carl Eckert reorganized the orchestra, and in 1860 the energetic otto Dessoff succeeded in bringing the orchestra to a high degree of perfection. Since then the *Philharmonische Concerte* have stood always for musical progress. The conductor in 1902 was Hans Richter, under whose leadership the society has established its reputation as one of the foremost orchestral institutions of the world.

BERLIN. The Berlin Philharmonic Society was founded by Edward Rietz (1802-32). This orchestra at first consisted of about forty instruments, but the number was subsequently increased and the organization now ranks with the best orchestras of Europe. Its concerts are given in the 'Philharmonie.' An innovation is its series of popular concerts given three times a week during the winter.

PHILHELLENES, fil-hĕl'lēnz (from Gk. φιλέλλην, *philellēn*, friend of the Greeks, from φιλεῖν, *philein*, to love + Ἕλλην, *Hellēn*, Greek). A name given to the friends of the Greeks in their struggle for independence. They were constituted into associations for the purpose of receiving and distributing gifts in aid of those engaged in the contest. The members came from all countries, including such men as Byron, King Louis I. of Bavaria, and a body of volunteers who fought for the Greeks under the leadership of General Normann-Ehrenfels.

PHIL'IDOR (1726-95). A famous French chess-player also known as a composer. His real name was François André Danican.

PHILINTE. fē'lant'. A character in Molière's *Misanthrope*, whose easy tolerance of the shortcomings of his fellows sets him in strong contrast to his friend Alceste.

PHIL'IP (Lat. *Philippus*, from Gk. Φίλιππος, Philip, loving horses, from *φιλεῖν*, *philein*, to love + *ἵππος*, *hippos*, horse). THE APOSTLE. One of the more prominent of the twelve disciples of Jesus. He was a fellow-townsman of Andrew and Peter and had been with them a follower of John the Baptist before he was called directly to become a disciple of Christ (John i. 43-44). When the company of the Twelve was definitely made up Philip became evidently one of their leading spirits, for his name stands in the lists at the head of the second of the three groups of four into which the Twelve are commonly divided. He does not figure extensively, however, in the records of the ministry of Jesus. His work after the death of Christ is involved in great confusion with that of Philip the Evangelist by the traditions. There are two apocryphal works bearing his name, the *Journeyings of Philip the Apostle* and the *Acts of Philip*. They are of slight historical value, however. Tradition of the safer sort assigns his labors to the region of Hierapolis in Asia Minor. The manner of his death and its date are both unknown.

PHILIP, THE EVANGELIST. One of those chosen by the first Christian church in Jerusalem to be the stewards of its charity to the widows and poor (Acts vi. 5). After exercising this office for a time he was engaged in missionary activity, which began after the death of Stephen. His initial work was among the Samaritans (Acts viii. 4-5). This was the first step outward from the limits of a Jewish cult for the new Christian faith. A second step in the process of widening the field was taken when Philip gave baptism to an Ethiopian eunuch (Acts viii. 26-40). Philip finally settled in the region of Cæsarea, on the coast of the Mediterranean, where he was found by Paul, who was entertained at his house (Acts xxi. 8). Tradition is not clear concerning his life after this, although there is pretty general agreement that he died a natural death at Tralles.

PHILIP II. (B.C. 382-336). King of Macedonia and father of Alexander the Great. He was born at Pella and was the youngest son of Amyntas II. and Eurydice. When a youth he was taken by Pelopidas as a hostage to Thebes, where he lived several years. After the murder of his eldest brother, Alexander, by Ptolemy Alcritas, he was appointed by his brother Perdiccas, when the latter, having slain Ptolemy, came to the throne, to the governorship of a separate district of the country. About B.C. 359 Perdiccas was slain in battle, while fighting with the Illyrians, and Philip assumed the government as guardian of his young nephew, Amyntas, the son of Perdiccas; but he soon set aside Amyntas and took the crown himself. At this time Macedonia was attacked on one side by the Illyrians, Pannonians, and other tribes, and on the other by the Athenians, while within she was torn by the dissensions of several pretenders to the throne; but, buying off the Thracians, who were supporting the pretender Pausanias; conciliating the Athenians, who had taken up the cause of another pretender, Argæus; killing or otherwise disposing of the remaining pretenders, and defeating in battle the threatening tribes, Philip in less than two years firmly established himself on his throne. Henceforward his policy was one of aggression, and the Greek towns on the coast of Macedonia were the first objects of attack. Amphipolis, Pydna, and Potidæa, Athenian possessions or allies on the coast of Macedonia, were the earliest places to fall into his hands. He then secured possession of the rich and valuable gold mines of Thrace, together with the town of Crenides, which he enlarged and called by the name of Philippi. These victories had all been obtained before 355; in 354 he took Methone, on the Thermaic Gulf, after a long siege, in the course of which he lost an eye, and then advanced into Thessaly, to aid the Aleuadæ against Lycophron, the tyrant of Pheræ. Defeating the force that was sent to oppose him, he established his supremacy throughout Thessaly and advanced as far south as the pass of Thermopylæ. The pass being guarded by a strong force of Athenians, who had been aroused by the eloquent warnings of Demosthenes, he returned and directed his arms against Thrace, where he succeeded in establishing his ascendency. In 349 he began his attacks on the Chalcidian cities, and in 347 completed the conquest of the Chalcidic peninsula by taking the city of Olynthus. In 346 he succeeded in gaining a further foothold in Greece, being called in by the Thebans to assist in the Sacred War against the Phocians. All the towns of Phocis, twenty-two in number, together with the pass of Thermopylæ, surrendered to Philip without resistance. The place which the Phocians had occupied in the Amphictyonic Council was transferred to him, and he was appointed, jointly with the Thebans and Thessalians, president of the Pythian games. In the following years he was again in Thrace, endeavoring to bring the cities in that country under his rule. He was unsuccessful in his attempt on Perinthus and Byzantium, and then turned his attention once more to the northern tribes. In B.C. 339 he was again invited into Greece, this time by the Amphictyonic Council, to take charge of the army that was to oppose the Locrians. Alarmed at his continued successes and his entrance into Greece, the Athenians formed a coalition with Thebes and other Greek States to oppose his advance, but the united army was utterly defeated at the battle of Chæronea in 338. This battle marks the end of Greek independence; Philip was now master of Greece. He at once began preparations for the invasion of Persia on a grand scale, and in 337, deputies from all the different States of Greece except Sparta assembling at Corinth, he was chosen commander-in-chief of the Greek forces. In the midst of his preparations, however, he was assassinated at Ægæ by a youth of noble blood named Pausanias, while attending a celebration in honor of the marriage of his daughter with Alexander of Epirus (B.C. 336). The motive for the deed, as stated by Aristotle, was private resentment for neglect on Philip's part to punish Attalus for a gross insult offered to Pausanias.

PHILIP III. A king of Macedonia. See ARRHIDÆUS.

PHILIP V. (B.C. 237-179). King of Macedonia, son of Demetrius II. and grandson of Antigonus Gonatas. He succeeded his uncle Antigonus Doson in 220. The first part of his reign was disturbed by the contentions of the Ætolian and Achæan Leagues; taking part with the latter, he conducted the war for several campaigns with ability and success. This war was called the Social War, and was concluded in 217, by the Peace of Naupactus. In 216-215 Philip was induced by the successes of Hannibal in Italy to conclude an offensive and defensive alliance with Carthage, the price of which was to be the Roman possessions in Illyria and the help of Carthage in his Grecian wars. The war which followed (214-205) is known as the First Macedonian War; at no time in the course of it did Philip render Hannibal any effective aid, and for the first three years the war was conducted on both sides with lack of energy. In 214 the Roman general, M. Valerius Lævinus, compelled Philip to raise the siege of Apollonia, and in 211 Rome organized against Macedon a coalition of Greek States with the Ætolian League at the head. Peace was concluded in 205 without material gain on either side. In 204 Philip made a bargain with Antiochus III. to divide between them certain of the dominions of the youthful King of Egypt, Ptolemy Epiphanes. This interference of Philip in the East precipitated the Second Macedonian War with Rome, which began in 200 and was brought to a close by the battle of Cynoscephalæ in 197. In this battle the Macedonian army was utterly defeated by Titus Quintius Flamininus; Philip was compelled to relinquish his conquests in Europe and Asia, to surrender his fleet, and to pay an indemnity of a thousand talents; Macedonia became an ally, subject to the control of Rome. Philip died in 179, and was succeeded by his son Perseus. Consult: Droysen, *Geschichte des Hellenismus* (2d ed., Gotha, 1877-78); Freeman, *History of Federal Government* (2d ed., New York, 1893); Mahaffy, *Alexander's Empire* (New York, 1888).

PHILIP I. (c.1052-1108). King of France from 1060 to 1108. He was the eldest son of King Henry I. and Anne of Russia. Until 1066, when Philip came of age, his mother and his uncle, Baldwin V. of Flanders, were regents. In the various contests of his great feudatories, to whom belonged William I. of England as Duke of Normandy, Philip often intervened successfully, so that the royal domain was increased until it extended from the valley of the Seine to the valley of the Loire, and also included Bourges. About 1071 Philip married Bertha, step-daughter of Count Robert of Holland. Though a son was born to them in 1081 (later Louis VI.), and afterwards a daughter, Philip nevertheless repudiated his wife in 1092, and began to live with Bertrada, the wife of Count Fulk of Anjou. The result was a continuous strife between the Papacy and the King. In 1095, at the Council of Clermont, Urban II. excommunicated Philip, though Bertha had died in 1094. This excommunication was raised after Philip had promised to put Bertrada away, but renewed in 1097, when he relapsed. In 1105, after Bertrada had died, he was released from the ban. Consult Luchaire, *Louis VI. le Gros* (Paris, 1890).

PHILIP II., or PHILIP AUGUSTUS (1165-1223). King of France from 1180 to 1223. He was the son of Louis VII. and Adèle of Champagne, and was born on August 21, 1165. He was crowned on November 1, 1179, during the life of his father, succeeded him in 1108, and proved one of the greatest monarchs of the Capetian dynasty. In 1181 he made war upon the Count of Flanders and in 1185 forced him to surrender the districts of Vermandois and Amiénois. In 1182 he drove the Jews out of his territories and confiscated all their wealth. In 1187 the English attempt to conquer Languedoc caused a war, in which Philip was aided by the sons of Henry II. (q.v.). After the accession (1189) of Richard to the English throne, Philip and he set out together on the Third Crusade (1190), but quarreled while wintering in Sicily, and their dissensions continuing, Philip, after a sojourn of three and a half months in Syria, set out on his return to France, after taking a solemn oath to respect the integrity of Richard's dominions. No sooner, however, had he returned than he entered into an arrangement for the partition of Richard's territories in France with his unworthy brother, John. Some acquisitions were made, but Richard's return thwarted the calculations of the conspirators, and a war immediately commenced between the two monarchs, in which Philip had at one and the same time to defend his territories against the English and the counts of Champagne, Boulogne, Brittany, and Hainault, who attacked them on all sides. Richard died in 1199; but on the appeal of the Barons of Poitou to Philip, as John's overlord, the war soon recommenced against John (q.v.). The English provinces in France were attacked by the combined French and Bretons, and Normandy, Poitou, Maine, Anjou, and Touraine were annexed to France. In the years 1213 and 1214 Philip waged war against Flanders and thus caused a coalition to be formed by Otho IV. (q.v.) of Germany, John of England, and the Count of Flanders. Philip defeated the allies in 1214 at Bouvines (q.v.). During the rest of his reign Philip was occupied in consolidating his new possessions, and took no part in the war against the Albigenses. In general Philip was in alliance with the Church and the great cities. His first wife was Isabella of Hainault, the mother of Louis VIII.; he next married Ingeborg of Denmark, but repudiated her in 1196 to marry Agnes of Meran. For this he was excommunicated and France was placed under an interdict. Philip yielded in 1200 and took back Ingeborg. He improved and embellished Paris, built many churches and other institutions, encouraged commercial associations, and gave the first charter to the University of Paris. He fortified many of the chief towns, including the capital. He died at Mantes, July 14, 1223. Philip was the first monarch under whom France attained a commanding position in Europe. Consult: Cartellieri, *Philip II., August* (Leipzig, 1899); Luchaire, *Philippe Auguste* (Paris, 1881).

PHILIP III., LE HARDI, i.e., the Bold (1245-85). King of France from 1270 to 1285. He was the son of Louis IX., and had his father's piety, but not his ability. He was an unimportant man personally, but his reign is noted on account of the rise of the lawyers as a class of royal advisers. Consult Langlois, *Le règne de Philippe III. le Hardi* (Paris, 1887).

PHILIP IV., THE FAIR (1268-1314). King of France from 1285 to 1314. He succeeded his father, Philip III. During his reign, which was of exceeding importance for the development of the French monarchy, he had three prominent advisers, Pierre Flotte, William of Nogaret, and Enguerrand of Marigny, who, being all taken from the rising legal class, were known as *légistes*. The event which stands out most prominently in this reign was the conflict with the Papacy under Boniface VIII. (q.v.). The French government sought to tax the clergy, whereupon Boniface interfered and issued the bull *Clericis laicos* in 1296, ordering the clergy to refuse obedience to the King. Boniface, it is true, gave way at once when a decree was issued forbidding the exportation of metals from France, the effect of which would have been to cut off a large portion of the Papal revenue, but the success of the Jubilee at Rome in 1300 induced Boniface to believe that he would find sufficient support in a struggle with Philip IV., and hence when in 1301 Bernard Saisset, Bishop of Pamiers, a Papal representative in France, was arrested there, Boniface issued his famous bull *Unam sanctam*. This set forth the highest Papal pretensions, and was a challenge to all monarchs of Europe. Philip, in order to be certain of support, summoned for the first time in the history of France the States-General. In 1303 while Boniface was at Anagni he was suddenly captured by William of Nogaret, and, though released the following day, he died soon after as a result of the shock. After the short rule of Benedict XI., Philip obtained in 1305 the election of his adherent, the Archbishop of Bordeaux, to the Papal chair, as Clement V. In 1309 the Pope took up his residence at Avignon, and until 1378 the Papacy was entirely under French influence, this being the period of the so-called Babylonish Captivity. See PAPACY.

On account of the increased expenditures of the monarchy, due to its greater extension and enlarged duties, it was found more and more difficult to carry on the government with the old revenues alone. A temporary expedient was found by compelling Clement V. to condemn the wealthy Templars and deliver their property over to the French King. Philip early in his reign had difficulties with Edward I. of England. In 1294 he took possession of Guienne, Edward's territory, and in 1297 attacked Guy, Count of Flanders, who had supported the English monarch. Boniface VIII. brought about a truce in 1298, and Guienne was restored to Edward. When, however, Guy of Flanders appeared in Paris in 1300 to submit, Philip cast him into prison. His officials treated the wealthy Flemish cities so harshly that they revolted under Peter of Koninck. Philip's army was decisively defeated at Courtrai (q.v.) in 1302, and in 1305 he made peace, restoring Flanders to the son of Count Guy, the latter having died in prison.

Scholars have long disputed concerning the true character of Philip. On the one hand he has been represented as an avaricious, scheming monarch; on the other as a mild man, who was completely in the hands of bold counselors. But concerning the results of his reign there is no question. Feudalism was suppressed, and the power of the Crown vastly extended. In order to meet the financial needs of the State, the taxes were increased, the Jews persecuted, and their property confiscated; and when these means were insufficient, the coinage was debased. Consult: Boutaric, *La France sous Philippe le Bel* (Paris, 1861); Funck-Brentano, *Philippe le Bel et la Flandre* (ib. 1896); Jully, *Philippe le Bel* (ib., 1869).

PHILIP V., LE LONG, i.e. the Tall (c.1294-1322). King of France from 1316 to 1322. He was the second son of Philip IV., and on the death of his brother, Louis X., was made Regent, as the Queen was with child. Her son died four days after birth and Philip proclaimed himself King (1316). Many opposed him, supporting the claims of his niece, the daughter of Louis X. The States-General, summoned by Philip in 1317, declared that women could not succeed to the throne. (See SALIC LAW.) In the same year Philip settled the long dispute with Flanders and acquired some territory from its Count. In 1320 a large number of peasants, known as Pastoureaux, led by some renegade clerks, demanded to be taken on a crusade. They committed horrible outrages, but were finally suppressed. Philip's reign is noteworthy for its many administrative reforms. He centralized the treasury receipts at Paris, suppressed the garrisons in castles not on the frontiers, confiscated for the Crown many feudal rights of taxation enjoyed by the nobles, and organized the army more efficiently. In other attempted reforms he was thwarted by opposition from the States-General. Consult Lechugeur, *Histoire de Philippe V. le Long* (Paris, 1897).

PHILIP VI. (1293-1350). King of France from 1328 to 1350, the first King of the House of Valois. He was the son of Charles of Valois, younger brother of Philip IV. At first Regent of France on the death of Charles IV., the proclamation of a king being deferred on account of the pregnancy of Charles IV.'s widow, he was crowned at Rheims on May 29, 1328, after the Queen had given birth to a girl. His right to the throne was denied by Edward III. of England, the grandson of Philip IV., who declared that females, though excluded by the Salic law, could transmit their rights to their children, and, therefore, insisted upon the superiority of his own claims. Philip's reign commenced gloriously, for, marching into Flanders to support the Count against his rebellious subjects, he wiped out the disgrace of Courtrai by vanquishing the Flemings at Cassel, August 23, 1328. The relations with England were very strained, and in 1337 the Hundred Years' War (q.v.) began, mainly through Philip's own fault. It was carried on languidly for several years, the only prominent incident being the destruction of the French fleet off Sluis, June 24, 1340. Philip was very extravagant and delighted in maintaining a brilliant court. The constant round of fêtes and tournaments was never interrupted, even when the war had well nigh exhausted the wealth of the country, for the money to carry them on was immediately provided by some new tax, by an arbitrary change in the coinage, or by some fresh confiscation. In 1338 the States-General declared that their consent was necessary for the imposition of new taxes, but Philip evaded all restraints which were imposed. In 1346 Edward III. landed in Normandy, ravaged the country to the environs of Paris, and totally defeated Philip at Crécy (q.v.). A truce was

then concluded by Papal mediation in 1347, but the kingdom had no sooner been released from war than destruction in another and more terrible form, that of the 'black death' (q.v.), appeared. Nevertheless the extravagance at the Court was as great as ever. During Philip's reign the royal domain was increased by the addition of Valois, Chartres, Anjou, Maine, Champagne, Brie, and Dauphiné, but diminished by the exchange of Navarre for Champagne and Brie. Consult Lavisse and Rambaud, *Histoire générale*, vol. iii. (Paris, 1894), for a good general sketch and bibliography. See FRANCE.

PHILIP II. (1527-98). King of Spain from 1556 to 1598. He was born at Valladolid on May 21, 1527, the only son of the Emperor Charles V. (q.v.). His education was chiefly in the hands of the clergy and he grew up a cold and bigoted man. In 1543 he was married to Maria of Portugal, and upon her death he espoused in 1554 Mary I. of England (q.v.). In 1555 Charles V. surrendered the government of the Netherlands to Philip, and in the following year resigned also the crown of Spain to his son, who had been previously invested with the sovereignty of Naples, Sicily, and Milan. The possession of Spain in the New World included the West Indies, Mexico, and a great part of South America. The early part of the reign of Philip proved very successful. He defeated a coalition formed against him by the Pope and France, his armies winning several battles, notably that of Saint-Quentin (1557), and France was compelled to sign on April 2-3, 1559, the Treaty of Cateau-Cambrésis (q.v.), which marked the abandonment of her rôle as an aggressive power on the side of Italy. Philip determined to stamp out opposition to Roman Catholicism in all his dominions, and this caused the revolt of the Netherlands (q.v.). This successful rebellion, and the enormous expenses it entailed upon Spain, ruined the prosperity of Philip's dominions. The naval supremacy of Spain, moreover, was shattered by the defeat of the Armada (q.v.), which Philip had sent against England in 1588. Besides the war against England, Philip was led by the affairs in the Netherlands to interfere also in the concerns of France. He has been sometimes accused of having instigated the Massacre of Saint Bartholomew, and he supported the Guises against Henry of Navarre (later Henry IV.), but all in vain. On May 2, 1598, the Treaty of Vervins (q.v.) was concluded with France. Against the Turks Philip was more successful. They were decisively defeated in 1571 by his half-brother, John of Austria, commanding the fleet of the Holy League (Spain, Venice, the Papal States), at Lepanto (q.v.). Portugal was conquered by Philip's general, the Duke of Alva (q.v.), after the direct male line of that country had become extinct in 1580. But these successes were unable to outweigh the ruin of Spanish commerce and industry. Philip died after a lingering illness on September 13, 1598. After the death of Mary of England in 1558, Philip married in 1559 Elizabeth, the daughter of Henry II. of France, and when she died in 1568, he married Anna, a daughter of the Emperor Maximilian II. By his first wife Philip had a son, the celebrated Don Carlos (q.v.), and by his fourth wife, his successor, Philip III. (q.v.). Philip II.'s character has been the subject of considerable historical controversy. There can be little doubt that he was bigoted and morose, but, on the other hand, the popular view, which represents him as a cruel monster, is a false one. He seems to have been an idealist and a visionary, who believed firmly that he was benefiting humanity by his drastic measures. He was often open to appeals for mercy and leniency, but the Inquisition was permitted a free sway in Spain, and all liberty was crushed.

Consult: Prescott, *History of the Reign of Philip II., King of Spain* (Boston, 1855-56), which is valuable, but incomplete; Forneron, *Histoire de Philippe II.* (Paris, 1881-82); Philippson, *Westeuropa im Zeitalter von Philipp II., Elisabeth und Heinrich IV.* (Berlin, 1882); Mignet, *Antonio Perez et Philippe II.* (Paris, 1874); Lobkowitz, *Philippus Prudens* (Antwerp, 1639); Gachard, *Correspondance de Philippe II. sur les affaires des Pays-Bas* (5 vols., Brussels, 1848-79); id., *Lettres de Philippe II. à ses filles les Infantes Isabelle et Catherine* (Paris, 1884); id., *Correspondencia de Felipe II. con sus embajadores en la corte de Inglaterra, 1558-8* (4 vols., Madrid, 1888). See SPAIN.

PHILIP III. (1578-1621). King of Spain from 1598 to 1621. He was the son of Philip II. and is to be remembered chiefly for accelerating the ruin of Spain, which had begun under his father, by driving out in 1609 the Moriscos (q.v.), the most industrious and thrifty inhabitants of Spain.

PHILIP IV. (1605-65). King of Spain from 1621 to 1665. He took little part in the affairs of government, which from 1623 to 1643 were in the hands of his favorite Olivarez (q.v.). In spite of the latter's efforts for the encouragement of trade and industry, the decline of Spain was hastened by exhausting wars in Germany and with France. In 1640 Portugal conquered its independence, and by the Treaty of Westphalia Spain acknowledged the independence of the Netherlands. The Peace of the Pyrenees in 1659 was highly favorable to France. Philip's reign was disturbed also by insurrections in Catalonia and Andalusia.

PHILIP V. (1683-1746). King of Spain from 1700 to 1746, first of the Spanish Bourbon dynasty. He was directly descended on both sides from Philip II., and was born at Versailles, December 19, 1683, the son of the Dauphin Louis and Maria Anna of Bavaria, and grandson of Louis XIV. and Maria Theresa, eldest sister of Charles II. of Spain. The Archduke Charles of Austria, second son of the Emperor Leopold I., stood equally near the Spanish succession; but Charles II., dying without issue, left the kingdom by his last will to Philip, then Duke of Anjou (1700). Philip was at once proclaimed at Fontainebleau and at Madrid as Philip V. To defend this succession, which threatened to disturb the religious political balance in Europe, France and Spain became involved in war with the Grand Alliance, formed by England, Holland, and Austria, and joined by Prussia, Denmark, Hanover, Portugal, and finally Savoy. (See SUCCESSION WARS.) The Peace of Utrecht (April 11, 1713) secured the throne of Spain to Philip, but shorn of the Italian possessions and the Netherlands. Philip V. was distinguished 'for few faults and few virtues,' was weak minded, and became almost imbecile before his death. His first wife, Marie Louise of Savoy, died in

1714, and with her death ended the influence the Countess Orsini had acquired over him, for Philip married Elizabeth Farnese of Parma, an energetic and ambitious woman. Her schemes for advancing the interests of her sons kept Spain embroiled throughout the reign. The minister Cardinal Alberoni (q.v.) directed his policy toward regaining the lost Spanish possessions in Italy and had to be removed because of the hostility aroused among the powers. In 1724 Philip abdicated in favor of his eldest son, Louis, but upon the death of the latter in the same year he resumed the crown, notwithstanding his increasing incapacity. In 1734-35 Don Carlos, son of Philip, wrested the Two Sicilies from Austria. In 1741 Spain entered into an alliance with France against Maria Theresa in the War of the Austrian Succession. (See SUCCESSION WARS.) Philip died at Madrid on July 9, 1746. He was succeeded by his second son, Ferdinand VI. (q.v.). Consult: Coxe, *Memoirs of the Kings of Spain of the House of Bourbon from the Accession of Philip V. to the Death of Charles III.* (5 vols., London, 1815), a work that is still of value, although new sources have come to light since it was written; Boudeillart, *Philippe V. et la cour de France, 1700-15* (Paris, 1890). See SPAIN.

PHILIP OF SWABIA (c.1177-1208). An emperor of the Holy Roman Empire. He was the youngest son of Frederick Barbarossa and Beatrice of Burgundy. He was educated for the Church and in 1191 became Bishop of Würzburg. In 1192 he resigned his see. His brother, the Emperor Henry VI., gave him Tuscany in 1195 and in 1196 he succeeded to the Duchy of Swabia. In 1197 he married the Byzantine Princess Irene. On the death of Henry VI., in 1197, Philip endeavored to secure the Imperial crown for his brother's infant son, Frederick (II.), but the German princes were unwilling to place the child on the throne, and Philip himself was chosen Emperor in 1198. But the Guelphs, under the leadership of Adolf, Archbishop of Cologne, put forward as a candidate Otho of Brunswick, who was crowned two months before Philip (1198), and in 1201 gained the support of Pope Innocent III. Philip fought bravely against great odds, and by bribes won over the Archbishop of Cologne and Hermann of Thuringia, with other powerful princes. In 1205 he was crowned by the Archbishop of Cologne, and captured the city, but let his rival slip through his fingers (1206). He made terms with Otho and with Innocent III. The former broke his promises, and Philip, making ready to attack him, was assassinated by Otho of Wittelsbach. Consult Winkelmann, *Philipp von Schwaben und Otto IV. von Braunschweig* (Leipzig, 1873-78).

PHILIP THE BOLD (1342-1404). Duke of Burgundy from 1363 to 1404. He was the fourth son of John the Good, King of France. He was present in 1356 at the battle of Poitiers (q.v.), and displayed such courage, venturing his own life to save that of his father, that he became known as *Le Hardi*, i.e. 'the Bold.' He shared his father's captivity in England, and on returning to France in 1360 received in reward of his bravery the Duchy of Touraine, and subsequently (1363) also that of Burgundy, being created at the same time the first peer of France. In 1369 he married Margaret, the daughter and heiress of Count Louis de Mâle of Flanders. On the death of King Charles V., in 1380, he became Regent, together with his brothers, for his nephew, Charles VI. In 1382, at the head of a French army, he marched against Philip van Artevelde, the leader of the Flemish burghers in their revolt against their Count, and overwhelmed him in the battle of Roosebeke. Flanders, Artois, and Franche-Comté fell to him by the death of Louis in 1384. Energy and wisdom characterized his government; arts, manufactures, and commerce were encouraged, and his land was one of the best governed in Europe. When Charles VI. became insane (1392) the supreme control of affairs in France fell into the hands of Philip, and he used his power to strengthen his own line. He died at the château of Hall in Hainault, April 27, 1404. Consult Lavisse and Rambaud, *Histoire générale*, vol. iii. (Paris, 1894), and bibliography. See also FRANCE.

PHILIP THE GOOD (1396-1467). Duke of Burgundy from 1419 to 1467. He was the son of John the Fearless and Margaret of Bavaria. He was born at Dijon, June 13, 1396, and on the assassination of his father on the bridge of Montereau, succeeded to the Duchy of Burgundy. Bent on avenging the murder of his father, he entered into an offensive and defensive alliance with Henry V. of England at Arras in 1419, recognizing him as the rightful Regent of France, and heir to the throne after Charles VI.'s death. This agreement was sanctioned by the imbecile King himself as well as by the mother of the Dauphin, Queen Isabella, in the Treaty of Troyes (1420). The Dauphin (later Charles VII.), however, declined to resign his rights, and took to arms, but was defeated and driven beyond the Loire. Some disputes with the English concerning possessions in Brabant and elsewhere prompted Philip to threaten in 1429 to conclude a treaty with Charles VII. However, the English, by ceding to Philip the Province of Champagne, and paying him a large sum of money, restored him to their side. In 1429-30 Namur, Brabant, and Limburg were annexed to Burgundy, and in 1433 Countess Jacqueline ceded Hainault, Holland, and Zealand to Philip. Though much more powerful than his nominal superior, the King of France, Philip did not take the royal title. After the death of his wife, sister of the English Regent in France, the Duke of Bedford, he gradually drew nearer to Charles VII., and in 1435 tried to negotiate a peace at Arras between all parties in the Hundred Years' War. The English demands proving excessive, he made peace alone with the French King. The latter part of his reign was filled with trouble caused by the quarrels between Charles VII. and his son, the Dauphin Louis, afterwards Louis XI. (q.v.), who had fled from his father's Court, and sought shelter with Philip. Philip died at Bruges, July 15, 1467, deeply lamented by his subjects. Under him, Burgundy was the most wealthy, prosperous, and tranquil State in Europe; its ruler was the most feared and admired sovereign of his time, and his Court far surpassed in brilliancy those of his contemporaries. Knights and nobles from all parts of Europe flocked to his jousts and tournaments. In 1430, in honor of his marriage with Isabella of Portugal, his third wife, he established the famous order of the Golden Fleece (q.v.). De Barante, *Histoire des ducs de Bourgogne*, vols.

iii.-vi. (2d ed., Brussels, 1834-40). See CHARLES VII.

PHILIP THE MAGNANIMOUS (1504-67). Landgrave of Hesse from 1509 to 1567. He was born on November 13, 1504, and succeeded to the throne on the death of his father, William II. In 1518 he began to govern in person. At first he showed no sympathy for the Lutheran doctrines, of which he was to become the champion, and in 1523 he married the daughter of the Catholic Duke George of Saxony. In 1525, however, he was definitely won over to the cause of the Reformation. At the same time he aided in supressing the Peasants' War. Philip became one of the chief leaders of the Reformation in Germany, and together with the Elector John of Saxony formed in 1526 the Protestant League of Gotha and Torgau. In 1529 he arranged the celebrated disputation between Luther and Zwingli at Marburg. It lasted for three days (October 1st-3d), but the two parties were unable to agree on the doctrine of the Eucharist. Philip himself, however, began to lean strongly toward the Swiss side. In 1531 he formed together with the Elector of Saxony and other Protestant princes the League of Schmalkald (q.v.). On March 4, 1540, Philip married a second time, though his first wife was still living. Luther and Melanchthon had consented to this bigamy, and the revelation of this fact caused a great scandal. In the Schmalkald War, which broke out in 1546, Philip did his best for the Protestant cause, but the treachery of Maurice of Saxony, his son-in-law, who joined Charles V., made matters hopeless. At the battle of Mühlberg on April 24, 1547, Philip was made prisoner and placed in close confinement. He was liberated in 1552 by the action of Maurice, who deserted Charles and rejoined the Protestant cause. Philip died on March 31, 1567, leaving four sons, among whom Hesse was divided. Consult: Rommel, *Philipp der Grossmütige, Landgraf von Hessen* (Giessen, 1830); Ranke, *History of the Reformation in Germany* (Eng. trans., London, 1845-47); Janssen, *History of the German People at the Close of the Middle Ages* (Eng. trans., ib., 1896—).

PHILIP THE MAGNANIMOUS, ORDER OF. A Hessian order of merit with five classes, founded by Grand Duke Ludwig II. in 1840. The decoration is an eight-pointed cross of white enamel, with the motto *Si Deus nobiscum, quis contra nos.*

PHILIP, KING (?-1676). A famous Indian chief, son of Massasoit; called by the English King Philip, though his Indian name was Metacomet. He became sachem of the Wampanoags, who were settled in the Rhode Island country in 1662, and in the same year went to Plymouth and promised to maintain friendly relations with the English colonists and not to cede any territory without their knowledge. About 1670 his friendly intentions began to be suspected on account of frequent meetings of the tribes and many murders of white settlers. In view of these suspicions, Philip and the principal tribesmen were summoned to meet the whites and explain their movements. This they did, and also agreed to surrender their arms; but it was only a truce, and preparations for war were still secretly carried on by the Indians. An Indian convert named Sausamon revealed to the colonists the preparations made by Philip, and was murdered by the Indians. In revenge for the execution of his murderers by the whites, the Indians killed eight or nine colonists, and open hostilities were begun in June, 1675. The Indians did not venture to meet the colonists in battle, but burned or attacked a number of their settlements, including Swansea, Brookfield, Deerfield, and Hadley, and laid ambuscades for the settlers. In December, 1675, Governor Josiah Winslow led a force of 1000 men against the Narragansets, with whom Philip had formed an alliance, took by storm a fort said to have contained 4000 Indians, near the present location of Kingston, R. I., destroyed their village of 500 wigwams, and put to death 500 of their warriors and twice as many Indian women and children. The war went on for the first six months of 1676, and was marked by burnings and massacres at Weymouth, Groton, Medfield, and Lancaster, Mass., and at Warwick and Providence, R. I. But the increased efforts of the colonists soon struck demoralization into the ranks of the Indians. A substantial reward was offered by the Government for every Indian killed in battle, and many Indian women and children were captured and sold into slavery. A force under the command of the great Indian fighter Capt. Benjamin Church (q.v.) hunted Philip from place to place, at last locating him through the aid of a friendly Indian in a swamp near Mount Hope, where he was killed by another Indian while trying to escape. His body was quartered, on a Thanksgiving Day especially appointed, and his head was sent to Plymouth, where it was long kept on a gibbet. During this war some 600 colonists were killed, 600 buildings burned, and 13 towns destroyed, but of the two once powerful Indian tribes it is said that less than 200 individuals were left. The cost of the war was estimated at $1,000,000. Consult: Fiske, *The Beginnings of New England* (Boston, 1889); Palfrey, *History of New England* (ib., 1864); and Doyle, *The English Colonies in America*, vol. iii. (New York, 1889).

PHILIP, GOSPEL OF. See APOCRYPHA, section on *New Testament.*

PHILIP, THE ADVENTURES OF. A novel by Thackeray (1862). This sequel to *The Shabby Genteel Story* appeared in the *Cornhill Magazine* (1861-62). Philip Firmin, the attractive, high-spirited hero, was almost ruined by his unspeakable father, the doctor, ignored by his relatives, helped by the Pendennises, and happily married to Charlotte Bayne.

PHILIP, JOHN WOODWARD (1840-1900). An American naval officer, born in New York City. He was appointed to the United States Naval Academy at the age of sixteen, became midshipman in 1861, and during the Civil War served in the Gulf blockading squadron, the James River fleet, and the South Atlantic blockading squadron, acting as executive of the *Chippewa*, *Pawnee*, and *Montauk* at the siege of Charleston. In July, 1862, he was promoted to be lieutenant, and in July, 1866, to be lieutenant commander. After the war he was executive successively of the *Hartford* and the *Richmond*, was placed in command of the *Monocacy* in June, 1873, and in December, 1874, was commissioned commander. From 1874 to 1876, on leave of absence, he commanded one of the steamers of the Pacific Mail Steamship Company, running between San Fran-

ense and Hong Kong, and in 1877, again on a leave of absence, he commanded the 'Woodruff Scientific Expedition Around the World.' He was promoted to be captain in 1889, commanded the Boston Navy Yard from 1894 to 1897, and in the latter year was placed in command of the battleship *Texas*, which, still under his command, took a prominent part in the naval battle of Santiago during the Spanish-American War. In August, 1898, he was promoted to be commodore and was placed in command of the second squadron of the North Atlantic fleet, and in March, 1899, he was promoted to be rear-admiral and made commandant of the Brooklyn Navy Yard.

PHILIP NE'RI, Saint (1515-95). The founder of the Congregation of the Oratory (q.v.). He was born at Florence of a distinguished family, July 21, 1515. On the death of his parents in 1533, he was adopted as his heir by a wealthy relative, with whom he lived for a time at San Germano, near Monte Cassino. But he relinquished these prospects to devote himself to the service of God, and on the advice of the Benedictine monks of Monte Cassino, came to Rome to make his theological and philosophical studies (1534-37). He devoted himself to works of mercy, once sold his books to feed the poor, and in 1548, in conjunction with his confessor, Persiano Rosa, founded the Confraternity of the Holy Trinity to care for the needs of the vast numbers of pilgrims who came to Rome. This brotherhood is said to have provided hospitality for not less than 600,000 pilgrims in the jubilee year of 1625, and for a quarter of a million in 1825. (See Morichini, *Instituti di pubblica carità*, Rome, 1870.) Having long refused holy orders from motives of humility, he finally received them in 1551, and began as a priest a still more remarkable career of devotion and influence. Inspired by the tidings of the heroic labors and death of Saint Francis Xavier, he determined to go to the Indies, and assembled 20 companions; but he was finally convinced that Rome was meant to be the field of his work. The objects of the informal association out of which the Congregation of the Oratory later developed were the instruction and training of the young and uneducated. As a means of withdrawing them from dangerous amusements, sacred musical entertainments (hence called by the name of *oratorio*) were held in the oratory, at first consisting merely of hymns set to popular tunes, but afterwards partaking more of the nature of sacred dramas. The music was composed by the first musicians of Rome. Palestrina was a spiritual child of Philip's, and died in his arms. It was in the lectures originally prepared for use in the oratory that, at Saint Philip's instance, the gigantic Church History of Baronius had its beginning. The personal character of Philip, the unselfish devotion of his life, his unaffected piety, genuine love of the poor, kindly and cheerful disposition, and perhaps as much as anything else a certain quaint humor which pervaded many of his sayings and doings, contributed to popularize his work. The development of the Oratory was almost unconscious. In 1561 Philip was requested by his fellow-countrymen the Florentines in Rome to take charge of their Church of San Giovanni near the Ponte Sant' Angelo; he declined, until Pope Pius IV. gave him permission to hold it while still retaining his residence in his humble cell at San Girolamo. In 1574 the Florentines erected a new oratory near the church, and the exercises were held there for a time; the following year he saw himself compelled to provide for the permanence of his work on a larger scale, and, taking the small Church of Santa Maria in Vallicella, he pulled it down and built a large new one. Here he was authorized by Gregory XIII. to found a definitely organized congregation in the same year. He still remained at San Girolamo, and refused to appear as the head and founder of the new society, until in 1583 he was expressly commanded by the Pope to take up his residence in the new house. Then his associates elected him superior for life, despite all his protests. Ten years later, however, he prevailed upon them to let him lay the burden aside, and Baronius was chosen in his stead. He died May 26, 1595. Paul V. beatified him in 1615 and Gregory XV. canonized him in 1622. Called the Apostle of Rome, he remains to this day emphatically the popular saint of the Roman people, who observe his feast-day with great devotion. From 1726 until the Italian occupation, the popes were accustomed to go in solemn state on this day to visit his tomb and to say mass there. Consult the contemporary lives of Gallonio, Barnabei, and Bacci (the two first contained in the *Acta Sanctorum*); English translation of the last by F. W. Faber (London, 1847); a modern biography by Cardinal Capecelatro (Naples, 1879; Eng. trans., London, 1894); *Maxims and Counsels of Saint Philip Neri* (Dublin, 1890); Cardinal Wiseman, *Panegyric of Saint Philip Neri* (London, 1856).

PHILIPP, Isidor (1863—). A French pianist of Austrian birth. He was born at Pesth, but early removed to France. In 1879 he entered the Conservatory as a pupil of Mathias, and later studied under other famous teachers of that institution. He was intimately connected with the musical life of Paris, and did much to spread a love for classical chamber music. He was one of the most popular artists appearing at the Lamoreux concerts, and was equally well received throughout the large cities of France. In London and Brussels he was also highly esteemed. His published compositions have been successful, particularly his editions of classic studies. Together with Loeb and Berthelier, he organized a series of concerts given in the Salle Erard, which concerts were largely devoted to the presentation of new French compositions. He was also cofounder and subsequent president of the Société d'Art.

PHILIPPA OF HAINAULT, hā'nō' (c.1314-69). An English queen, wife of Edward III. and daughter of William the Good, of Holland and Hainault. She was married in 1328 to her cousin, Edward of England, by Papal dispensation, and brought him a large dower and valuable Continental allies during the war with France. It is said that she summoned the forces which defeated the Scottish troops at Neville's Cross (q.v.) in 1346. Philippa was mother of the Black Prince, Edward. She was a patron of Froissart and was very popular among the English common people. Queen Philippa is notable because she aided in maintaining and strengthening that close connection of England and Flanders, so important for English commerce.

PHILIPPE DE THAUN. See Thaun.

PHILIPPEVILLE, fē'lēp'vēl'. A fortified seaport and the capital of an arrondissement in the Department of Constantine, Algeria, 38 miles north-northeast of the city of Constantine, on the Gulf of Stora, between Cape Bonjaroun and Cape de Fer (Map: Africa, E 1). Laid out in 1838 by Marshal Valée, on the ruins of the ancient Russicada, it is one of the prettiest towns in Algeria, and thoroughly French in its character. Philippeville is the chief railway station for the Department of Constantine, and is connected by steamer with Marseilles and Algiers. It has several public offices, a large hospital and dispensary, Catholic and Protestant churches, public library and museum, theatre, etc. It has a distillery, tanneries, and cork manufactures. In the vicinity at Filfila are quarries of marble and iron mines. The town is an important entrepôt of the commerce of the east of Algeria and the Sahara, and the country in the vicinity is picturesque and fertile, producing grain, tobacco, cotton, and fruits. Its fine outer and inner harbors of 125 acres are protected by two breakwaters. The total annual value of its imports and exports is $17,500,000. Population, in 1901, 21,251.

PHIL'IPP GALEN, gā'len. See LANGE, ERNST P. K.

PHILIP'PI (Lat., from Gk. Φίλιπποι). A city of Macedonia. It was named after Philip II. of Macedon, who conquered it from Thrace, up to which time it had been called Crenides, or 'the place of fountains,' and enlarged it because of the gold mines in its neighborhood. It was situated on a high hill on the southern edge of a great plain, and about nine miles from the coast, where was the harbor Neapolis. With the rest of Macedonia it fell under the Roman power in B.C. 168, and was joined to the District of Amphipolis. In B.C. 42 it was the scene of the battles between Brutus and Cassius on the one side and Mark Antony and Octavian on the other, which resulted in the destruction of the former. In consequence of this victory, Augustus subsequently made it a Roman colony and conferred on its inhabitants the *jus Italicum*, which exempted them also from the land tax. Here about A.D. 50 the Apostle Paul founded a Christian church, to which is addressed the Epistle to the Philippians. An epistle to the same church is also preserved among the writings of Polycarp. The ruins are still called in Turkish Felib-edjik.

PHILIPPI, FELIX (1851—). A German dramatist, born in Berlin. He early entered journalism, and in 1875 removed to Munich, where he contributed to various French and German papers. After about 1884, however, he devoted himself almost wholly to the writing of plays, and ultimately became one of the most popular contemporary dramatists in Germany, his plays being produced also in other countries and being given with considerable success in the German theatres in New York City. As a playwright he is classed with the modern realistic school. His plays include: *Der Withrakat* (1884); *Irrlicht* (1885); *Dagmar* (1886); *Meerschlechten* (1888); *Das alte Lied* (1889); *Die Rhein Fran* (1891); *Der verlorene Sohn* (1892); *Wohlthäter der Menschheit* (1895); *Der Dornenweg* (1895); and *Wer Wars?* (1896).

PHILIPPIANS, EPISTLE TO THE. One of the New Testament letters, whose authorship is generally assigned to Paul. It was written to the church at Philippi to correct tendencies toward faction and self-seeking among its members (ii. 1-4, 14; iv. 2-5), to warn them against evil influences in their midst (iii.), to encourage and strengthen them in their Christian life and work (i. 12-30; ii. 12-16; iv. 1, 4, 6, 8), and to thank them for their practical ministry to the Apostle's needs in his imprisonment (iv. 10-19). It differs from the principal Pauline Epistles in the marked absence from its contents of controversial topics, while, on the other hand, it is unlike most of the subordinate writings of the Apostle in containing passages which have formed the gathering points of considerable theological debate. These are chiefly the notable Christological passage of the second chapter (vs. 5-11) and, though to a much less degree, the well-known soteriological passage of the third chapter (vs. 3-16).

In spite of the denial of the Epistle's Pauline origin by the Tübingen school (1845) and by as recent and able a scholar as Holsten (1898), the letter is to-day almost universally accepted as from the Apostle—its rejection by the modern Dutch school of criticism (1882) merely forming a part of their peculiar negative position with regard to all the New Testament books. A phase of this Dutch critical attack, however, is the denial of the Epistle's integrity, in which position certain outside the school have joined (Spitta, 1893; Clemen, 1894). But, though there are recognized difficulties in its sequence of thought, especially in the connection of the third chapter with its preceding and following context, the letter's unity is generally maintained by critics to-day. Scholars have almost without exception settled upon Rome, during Paul's first imprisonment, as the place and time of the Epistle's composition. Thiersch (1879) and Macpherson (1892) being practically alone among later writers in the assertion of an origin at Cæsarea before Paul's voyage to Rome.

That which may be said to be of chief interest in the criticism of the Book is the question of its relative order to the other Epistles of Paul's first Roman imprisonment. The opinion more generally in favor to-day is that it is the last of this captivity group. It is argued that (a) the large size of the Church of Rome (i. 12-14); (b) the evidence of success from Paul's evangelistic work (i. 12-18), which would follow the statements made in Colossians and Ephesians of desire for such success (Col. iv. 3-4; Eph. vi. 19-20); (c) the several journeys between Philippi and Rome involved in the Philippians' ministry to the Apostle (ii. 25-27; iv. 18); (d) the desertion of the Apostle by his friends (ii. 19-21), which shows itself to be the climax of Col. iv. 11 and at the same time stands in contrast to Col. iv. 10-14 and Philemon 23-24; (e) the expectation of the near approach of his trial and the decision for life or death (i. 20-22; ii. 17, 24-26; iii. 10)—that these all show more naturally a later rather than an earlier date of writing. On the other hand, it is held that the similarity of much of the contents of the Epistle to the characteristic thought of Romans, and of much of the contents of Colossians and Ephesians with that which marks the thought of the pastorals, show in both cases a state of mind on the Apostle's part which would most naturally fit in with a nearness in composition of the respectively related Epistles. Whatever may be said,

however, as to the reasonableness of either line of argument, it is quite clear that the passage regarding the variant preachers in Rome (i. 14-18), with its bearing upon the state of the Roman Church when the Apostle wrote his letter to it, must be fully understood before the question of the date of this Philippian letter can be finally settled. To this study is being directed to-day.

PHILIPPICS. See Cicero; Demosthenes.

PHILIPPINE ISLANDS. An archipelago forming the most northern group of islands in the Malayan or Eastern Archipelago. It lies wholly within the tropics. The land surface extends between latitudes 21° 10′ and 4° 40′ N., 1150 statute miles; the east and west limits are longitude 116° 40′ and 126° 34′ E., making about 650 miles. The most northern land in the Philippines is Y'Ami Island, of the Batanes group; the most southern is Balut Island, of the Sarangani Islands, south of Mindanao; the most western is Balabac Island, north of Borneo; and the most eastern is Sanco Point, on the east coast of Mindanao. The archipelago is bounded on the north and west by the China Sea, on the east by the Pacific Ocean, and on the south by the Sea of Celebes and the coastal waters of Borneo. It is 93 miles distant from foreign territory on the north (Formosa); 31 miles from Balambangan, an island near Borneo, on the south; 510 miles from the Pelew group (German) on the east, and 515 miles from Cochin-China (French) on the west.

The archipelago numbers about 1600 islands, most of them very small, and having altogether about 11,500 miles of coast line. Two of them, Mindanao and Luzon, are, however, classed among the larger islands of the world, and eleven islands, Luzon, Mindanao, Samar, Panay, Negros, Palawan (Paragua), Mindoro, Leyte, Cebú, Masbate, and Bohol, are of primary geographical importance. The others are mainly dependent islands or islets along the coast of the large islands or subordinate archipelagoes like the Sulu Islands. The area of the total land surface is computed at 127,853 square miles, or a little larger than the New England States, New York, and New Jersey together. Mindanao (45,559 square miles) and Luzon (43,075 square miles) comprise about seven-tenths of the total land surface, the area of the other leading islands being: Samar, 5198 square miles; Negros, 4839; Panay, 4752; Palawan, 4368; Mindoro, 4050; Leyte, 3872; Cebú, 1668; Bohol, 1400; and Masbate, 1230. The total water surface within the limits occupied by the archipelago is 705,115 square miles.

Topography. This immense labyrinth of islands forms that part of a vast submarine plateau which has emerged above the ocean. The surrounding waters are shallow, for the most part not over 200 feet in depth, showing that the wide plateau on which the islands stand nearly approaches the surface. But strewn here and there over the sea floor are troughs and hollows and wide depressions, particularly to the west of Luzon and Mindanao, where greater depths are found. There is nothing approaching oceanic depths till the eastern edge of the submarine plateau descends to the Pacific deeps from 100 to 300 miles east of the archipelago. In the south three lines of islands stretch like isthmuses between the main archipelago and the southern lands. In the northwest is the most regular and best developed of these isthmuses, stretching from Mindoro to North Borneo, the long, narrow island of Palawan forming more than half its extent. In the centre the Sulu Archipelago connects the western terminus of Mindanao with the northeastern point of Borneo; and in the southwest the great peninsula of Celebes with the Sanguir Archipelago and other islands forms another isthmus, sweeping around to the south of Mindanao. These ridges are extended throughout the archipelago in the form of mountain ranges, from south to north, and form a large part of its relief. From the southern coast of Mindanao to the north of Luzon the mountains are disposed in a line with or parallel to the southern isthmuses. The whole interior is essentially mountainous, the Cordilleras extending north and south, their highest peaks ranging from 3720 to 10,312 feet (Apo in Mindanao), with outliers and ramifications partly filling the gaps between the ranges. Narrow plains occur between the mountains and wider ones where the river valleys broaden near the coast, and are enriched with alluvial deposits. Mountains are the backbone of all the islands, though in Leyte there are no mountains of special prominence. Three ranges in Luzon and four in Mindanao are the dominating features in the topography of those largest islands. The wider plains are in the basins of the larger rivers of Mindanao and Luzon. Owing to the predominance of mountains, the area of tillable lands is not believed to be one-third of the total area.

Hydrography. In the smaller and narrower islands the mountain chain which is the backbone of each island is the great central water-parting, streams flowing to the sea on either side of it in short, straight courses. Mindoro, for example, has about 60 independent little rivers. The drainage of the larger islands is more complicated, the parallel arrangement of the mountain chains giving space for the development of considerable streams. Among them is the Rio Grande de Cagayan (q.v.), with a drainage basin of 16,000 square miles, or much more than one-third of Luzon. All the interior waters of Northeastern Luzon are tributary to the Cagayan, reaching the China Sea on the north coast of the island. All the interior waters of Central Luzon, south of the Cagayan basin, are included in the system of the Rio Grande de la Pampanga, which empties through a wide delta into Manila Bay. The mountains are so near the sea in East Luzon that the rivers of that coast are of small importance excepting the Bicol in the southeast, which floats small vessels; but in the northwest the

Agno has 11 feet of water on its bar at high tide, which gives some importance to the port of Dagupan at its mouth. The Pasig is only 12 miles long, but as it connects Bay Lagoon (q.v.), or Laguna de Bay, with Manila Bay through the chief port of the island, it is a commercial highway of importance. The river systems of Mindanao, confined within the parallel ranges, have chiefly a north and south direction and are more important for navigation than those of Luzon. The Rio Grande de Mindanao, one of the largest rivers in the Philippines, drains the central basin of the island, carries the waters of many tributaries to the Celebes Sea on the west coast, and is navigable for gunboats as far as Lake Lagusan. The Rio Agusan (q.v.) rises about 25 miles from the south coast, and reaches the sea on the north coast, nearly dividing the island. It is navigable for a few miles from its mouth. The most important lakes in Luzon are: Laguna de Bay, 25 miles long and 21 miles wide, which receives numerous small streams from the mountains around it, and Bombon, 14 by 11 miles in extent. Taal volcano rising amid its waters. The largest lakes of Mindanao are Maguindanao, in the centre, and Malanao, near the north coast. Smaller lakes are scattered over the islands.

CLIMATE. As the archipelago is wholly within the tropics, the climate is naturally very warm. From November to February inclusive, the most temperate months, the temperature ranges from 75° to 80° F. The hottest months are April, May, and June, when the monthly mean ranges between 81° and 83°. The intermediate temperatures are in March, July, August, September, and October, when the mean is from 79° to 81°. The temperature at Manila rarely rises above 100° in the shade, and does not fall below 60°. The prevailing atmospheric humidity intensifies the discomforts of heat, from which there is little relief in the three hottest months; but in December, January, and February the nights are fairly cool. As the mean temperature for the year varies merely by a few degrees, only two seasons are recognized. In the wet season, from June to October, five months, the rains are very heavy in the interior and on the west coast, because the moist southwest monsoon there prevails. The east coasts do not share in the excessive precipitation, because they are shielded by the mountains. In the dry season, from November to May, the comparatively dry northeast monsoon prevails, there are many fair days, and the precipitation is greatest on the east coast. The rivers often overflow their banks during the wet season and wide areas in the larger islands are submerged; but the floods are not feared so much as the cyclonic storms of wind and rain known as typhoons, which seldom occur south of 9° N. latitude, but north of that line sometimes destroy the lives of thousands of persons and wreck many vessels and villages. Cyclones are most frequent in July, August, September, and October, when these whirling winds from the Pacific occasionally sweep the whole archipelago north of Mindanao. The most terrific of these storms recorded in the Philippines struck Manila in 1882, traveling at a velocity of 140 miles an hour.

The danger from epidemic diseases is not great except for the occasional visitations of cholera, which is difficult to control, as has been proved since the United States acquired the islands. Smallpox is always prevalent, but very seldom attains wide-spread development. The bubonic plague has never gained a strong foothold, though in 1901-02 the most strenuous efforts were required to suppress it. Malaria is prevalent in some islands, especially Mindoro, Balabac, and parts of Palawan, Luzon, and Mindanao, but large districts are entirely free from it. Malarial fevers and digestive troubles are the chief diseases. On the whole the health of the natives is fairly good, but the climatic conditions, except in some districts, are not favorable to long residence by Americans or Europeans. It is fortunate that some places among the mountains afford health resorts to which white persons may go for recuperation. Such an asylum is the elevated plateau of the small province of Benguet, 150 miles north of Manila, where, during the hottest month of the year, the temperature is not over 70° F. at midday.

FLORA. The vegetable life is rich and varied, with very few distinctive species, but some plants that are transitional between the flora of Formosa on the north and Borneo on the south. Sixty species of large trees afford the most valuable hard woods for the use of the ship-builders and cabinet-makers. Many other trees are so hard that they cannot be cut by the ordinary circular saw. The bamboo grows in numerous varieties, and, as in other parts of the Malayan Archipelago, is indispensable to the natives. The cocoa palm flourishes everywhere and many of the ripe nuts are collected in rafts and floated to market. The oil is used in cooking and as an illuminant. Other palms are very numerous. The banyan is common and grows to enormous dimensions, and the cinnamon, clove, and pepper are found wild in the southern islands. About 1200 genera and 5000 species of plants have thus far been recognized by botanists. Economically the most valuable of the wild plants is Manila hemp, the fibre of a wild plantain (*Musa textilis*). The plant closely resembles the edible banana in appearance and grows best on shaded hillsides at moderate elevations. The export crop is raised on plantations, which yield, when carefully managed, an annual return of 30 per cent. on the capital invested. This fibre is not successfully raised elsewhere except on a few plantations in North Borneo. Practically all the cultivated plants of the South Asian island world are successfully raised, including rice, sugar, tobacco, coffee, cacao, maize, and sweet potatoes.

FAUNA. The islands are poor in indigenous mammals. The most important animal is the carabao or water buffalo, which is caught young, tamed, and universally employed as a draught animal, while his tough flesh is valued by the natives as meat. He is usually docile, but is slow and lazy and during the heat of the day will not work more than two hours at a time without his mud bath. The female gives abundant milk, from which *ghee*, a kind of butter is made. The hide makes valuable leather. The timarau, a small buffalo living in the jungles of Mindoro, has never been tamed; it often attacks and kills the larger carabao. A small humped variety of cattle are raised in large numbers for beef on some of the islands. Goats are common and are utilized both for milk and flesh. There are several species of deer, and both wild and domesticated hogs are very abundant. The larger horse as known in America and Europe, does not thrive, but the Philippine

pony, originally from Spain, is an excellent saddle horse, and useful in teams as a carriage horse, but not strong enough for heavy work. The carnivora have no large representatives, and only a small wild cat, two species of civet cats, and the binturong are conspicuous. The islands have nearly 600 species of birds, among which are the jungle fowl, hornbill, fruit pigeon, the snipe, curlew, and other waders; also the species of swift whose nests (edible birds' nests) are highly esteemed in China as an article of food. Marine fish are far more important than fresh-water fish and form the largest part of animal food, the natives also eating many varieties of 'shell fish.' The pearl oyster, yielding a considerable quantity of shell and jewels, is fished in the Sulu Archipelago. Crocodiles and snakes are abundant. Swarms of locusts sometimes devastate the fields, and rice and tobacco have other insect enemies.

Geology and Mineral Resources. The geology of the archipelago has not yet been systematically studied. In broad outline the islands appear to consist of ancient eruptive rocks that have been covered by volcanic outpourings of the Tertiary, Quaternary, and present epochs, and in the lower levels by alluvium. Fossils are not found in the higher altitudes, and deposits of marine fossils are of small extent in recent geological times. There are twenty-three well-known volcanoes, of which eleven are more or less active. The most famous among them, and perhaps the most beautiful volcanic cone in the world, is Mayón, or the volcano of Albay, near the Bay of Legaspi, in Southeastern Luzon. Mayón is 8274 feet in height, and some of its eruptions in the past three centuries have been very serious. The surrounding country has been well-nigh buried under its streams of lava, and its clouds of volcanic dust have been carried through the air as far as the coast of China. Another remarkable volcano is Taal, which is an island in the middle of Lake Bombon, Luzon, with an area of 220 square miles, built up from the bottom of the lake by the outpourings from several craters. The archipelago is a centre of seismic as well as volcanic energy, and the volcanic centres are often the sources of the severest earthquakes. Most of the very violent shocks from which Manila has suffered, for example, have radiated from the Taal centre. For the eighteen years 1880-97 there was an average of 53.4 earthquake days in the year, or 4.5 per month.

The mineral resources are supposed to be very large, but their extent is not yet known. Better transportation facilities and more capital and labor will be required to develop these sources of wealth. True coal has not been found, but the highly carbonized lignite of Tertiary age which takes its place is supposed to be the chief mineral product. It is a fairly satisfactory fuel for steamers, and is widely distributed over the archipelago, especially in Luzon, Mindoro, Masbate, Panay, Samar, Cebú, Negros, and Mindanao. At present it is mined chiefly in Cebú, where as soon as the transportation shall have been perfected the output is expected to be 5000 tons a month. Gold is found in many localities, and has long been mined by natives, employing very rude and wasteful methods. Explorations have proved that the alluvial deposits in many parts of Luzon, Mindanao, and other islands are extensive, and gold-bearing quartz is found among the mountains of Northern Luzon, in Mindanao, and elsewhere, some of it being crushed by the natives between heavy stones and the metal extracted by washing. The prospects of gold-mining in Luzon are very favorable. Copper ore is reported from many islands, but the deposits have not yet been worked to any extent. Iron ore is abundant in Luzon, Cebú, Panay, and other islands. Some of the ore of Luzon yields 85 per cent. of pure metal, but thus far the ores are almost unworked except to a small extent in Luzon. Silver occurs in association with lead; sulphur may be obtained in large quantities around some of the volcanoes; and salt, gypsum, and a few other minerals of commerce are found.

Agriculture. Though agriculture is the most important source of wealth, it is in a very backward condition. Farming implements are of the most primitive sort. The cultivator, farm roller, and many other implements were never seen in the Philippines till the United States authorities opened the Government experimental farm. The natives do not understand the use of fertilizers, and know so little about forage crops that all the fodder for the horses and mules in the Government service has been imported. The indolence of the natives has also been unfavorable to large agricultural development. Nearly all the tilled lands are between sea level and 700 feet above the sea. The staple products in order of importance are Manila hemp (abaca), tobacco, sugar, coffee, and rice. Hemp is produced chiefly in the provinces of Luzon south of Manila, in the islands of Samar and Leyte, and on a smaller scale in the other islands north of Mindanao, and on the north coast of Mindanao. The bast, or fibrous outer leaf, yields the coarse, strong fibre which is the best material for sailcloth and cordage. From the fibre yielded by the inner stalks are woven fabrics that are superior in softness and lightness. These fabrics are seldom exported, but the bast, of which, under the best conditions, 3000 pounds to the acre are produced, is the greatest export commodity, the average yearly shipments amounting to nearly 100,000 long tons. Cotton and ramie fibre are also produced to some extent, but cotton has declined, owing to the increased use of foreign textiles. Tobacco is of excellent quality, though it does not equal the favorite grades of the Cuban crop. The best leaf is grown on the wide plain of the Rio Cagayan (Isabela and Cagayan provinces), North Luzon. This favored tobacco region supplies most of the leaf sent to foreign lands or manufactured in Manila. The inferior, though good, tobacco grown in the more southern islands is chiefly consumed at home, but the leaf of North Luzon is famous throughout Southeastern Asia and many Western countries. Sugar-cane, grown in all the islands, is of great importance, and though it is cultivated with little intelligence, and raw sugar is produced by the crudest methods, its value for export is second only to that of hemp. The coffee of Luzon and Mindanao is of excellent quality, comparing favorably with Java, but the crop has declined on account of insect enemies. Rice is grown everywhere, and is the great food staple of the common people. It was formerly exported to China, but for years the supply has been short of the home demand, and large quantities are imported from Cochin-China. Maize thrives throughout the archipelago and is grown especially on land that is not fitted for rice. While its use as food is

increasing, many natives do not eat it. Among other products are cocoanuts, cocoa, wheat, indigo, sesame, peanuts, many varieties of vegetables, and spices in the south. Large quantities of copra, the dried meat of the cocoanut, are prepared for export. The pastoral industries are extensive. Some of the islands, as Masbate, have comparatively little tilled ground and depend more largely upon live stock. It is estimated that Masbate has 10,000 carabaos, 55,000 cattle, and 5000 horses. Cattle of a small humped variety are raised for beef on several islands. Swine and fowls are found in every native settlement. The Government experimental farm near Manila is for the purpose of encouraging the production of crops. Experiments with alfalfa and other forage plants have been very successful, and most of the vegetables grown in the United States, excepting melons and white potatoes, yield well. The Government distributes seeds and is giving special attention to coffee-growing. Very little land is owned by the peasantry, who rent their small holdings, paying half the crop to the owners. About 500,000 acres of the best tillable lands are owned by three of the Roman Catholic societies which do not encourage thrifty farming; it is likely that their lands will be purchased by the Government and sold to the tenants. The settlement of the land question is of the highest importance, as it is impossible in most cases to give a safe title to lands.

MANUFACTURES. The most important manufactures are the products of the tobacco works. The largest tobacco factory in Manila has over 10,000 employees. Most of the natives smoke home-made cigars, and over 150,000,000 cigars are annually exported. The leaf is cured and manufactured by means of modern machinery, many of the cigarette machines are worked by steam, and Manila is the chief centre of all tobacco products. Fabrics of Manila hemp, wool, cotton, silk, and piña fibre are woven on hand looms; and bamboo, rattan, palm leaves, and other material are used with intelligence and skill in making mats, hats, bags, cigar cases, and a large variety of other articles. Rope, soap, leather, sugar, and some other commodities are made by antiquated and imperfect processes, but much skill has been developed in erecting the better class of buildings, and in making furniture and wood carvings.

COMMERCE. Trade relations with foreign countries have grown rapidly since law and order were restored throughout most of the islands about the beginning of 1900, as the following table, giving the value of exports and imports, shows:

	1900	1901	1902
Exports	$19,751,068	$23,214,948	$29,000,000
Imports	20,601,436	30,279,406	34,342,166

The large increase in the trade between the Philippines and the United States is shown by the following table:

	1898	1899
Exports to the United States	$3 [illegible] 415	$4,409,774
Imports from the United States	127 804	404 193

	1900	1901	1902
Exports to U. S.	$5,971 208	$4,420,912	$6,632,700
Imports from U. S.	2,640,449	4,027,004	5,251 867

The trade in 1901 with the other countries that are most important in Philippine commerce is indicated in this table:

	United Kingdom	Hong Kong	British East Indies
Imports from	$6,956,145	$4,529,322	$2,820,797
Exports to	10,704,731	5,067,547	1,314,084

	Spain	France	French East Indies
Imports from	$2,166,866	$1,684 233	$1,914,238
Exports to	1,656,409	1,934,256	1,486

The exports consist very largely of agricultural products. Manila hemp and sugar, the leading staples of the islands, are the principal factors in the trade, their combined value usually amounting to more than 75 per cent. of the total export valuation. In 1900 the value of the principal exports was: Manila hemp, $13,290,400; sugar, $2,397,144 (smaller than usual); copra and cocoanuts, $3,184,853 (unusually large); cigars and cigarettes, $1,164,369; leaf tobacco, $1,033,900; hides and skins, $311,183. The exports were classified as: Products of agriculture, 87 per cent.; manufactures, 7 per cent.; miscellaneous, 6 per cent.

The imports are chiefly manufactured articles, cotton goods usually forming one-third to nearly one-half of the total, and foodstuffs. Rice is the most important of the agricultural imports. The value of the chief imports in 1900 was: Cotton manufactures, $8,727,777; rice, $4,365,056; iron and steel articles, $1,425,233; wheat flour, $475,236; malt liquors and cider, $1,113,684; mineral oils, $374,717; silk manufactures, $385,984; glass and glassware, $395,620.

Manila hemp is almost the only article imported into the United States, the value of the fibre brought to this country in 1902 amounting to $6,318,470.

Great Britain leads in the foreign trade with the Philippines, chiefly on account of its large purchases of Manila hemp and its surpassing sales of cotton cloth. The United States supplies more foodstuffs, excepting rice, which comes from Cochin-China, than any other country; and its sales of iron manufactures to the islands in 1902 amounted to $957,342. In the same year the imported foodstuffs amounted to over $14,000,000, or about two-fifths of the total imports.

TRANSPORTATION AND COMMUNICATION. The three leading ports of the islands are Manila, Cebú, and Iloilo. The situation of Manila (q.v.) gives it superior advantages in the domestic and foreign trade of the islands. Vessels, however, having a draught of more than sixteen feet are compelled to anchor two miles from the shore, and are dependent upon lighterage for loading and unloading cargoes. The Government intends to dredge an inshore harbor and protect it by breakwaters, so that the largest vessels may tie up at the docks. Cebú and Iloilo are the chief ports of the islands of Cebú and Panay, respectively, in the Visayan or great central group of islands between Luzon and Mindanao. There are also three ports of secondary importance: Aparri, on the north coast of Luzon, a large centre of tobacco shipments; Zamboanga, the leading port of Mindanao; and Jolo, the chief port of the Sulu Archipelago, in the south. Custom houses are maintained at these six ports, and

they are open to foreign trade. In addition to these ports there are a large number of local ports whose business is confined to the coastwise trade. Many of them are connected directly by small steam and sailing vessels with the ports engaged in the foreign trade. As the islands lack railroads and have very few roads of any description, they are dependent upon this large coasting trade for the distribution of their domestic commerce or for the dispatch to or receipt from foreign countries of articles in the foreign trade. Thus the leading ports are the forwarding and distributing points for the entire over sea commerce. There are, for example, about thirty local ports at which the Manila hemp crop is collected for shipment to Manila, Iloilo, and Cebú, where it is transferred to vessels in the foreign trade. The freight rates on these coasting lines are high.

All the ports are reached from the interior by small rivers, or by bad cart roads or footpaths. These paths and trails extend from the ports in all directions, but are very inadequate, and commerce is hampered by the poor inland communications. The only railroad extends from Manila north to Dagupan, on Lingayen Bay, 120 miles. It is estimated that the islands require at least 1000 miles of railroad as a factor in their development.

The islands are fairly well supplied, through the three leading ports, with transportation to foreign lands. They have direct steam communications with all the leading ports of South Asia, Australia, San Francisco, and Barcelona, Spain. A large amount of the freight, however, is transhipped at Hong Kong and other Asian points, where it meets the steamships of the regular lines in the European and American trade. In 1901, 789 British, German, Chinese, and other foreign vessels entered the ports of Manila, Iloilo, and Cebú. Very little of the trade even with the United States is carried in vessels flying the American flag. In 1902 about 94 per cent. of American sales to the Philippines and 99 per cent. of American purchases were carried in foreign bottoms. Since August, 1898, the Signal Corps of the United States Army has laid 1327 miles of cables between the islands and 5000 miles of permanent telegraph lines, so that most parts of the archipelago have now the means of rapid communication with one another. In 1903 direct electrical communication with the United States was opened by means of a Pacific cable between the east coast of Luzon and San Francisco by way of Guam, Midway Island, and Honolulu. Manila is also connected by cable with Hong Kong and the European system.

BANKING. There are three general banking corporations in the islands. The Banco Español-Filipino, at Manila, with a branch at Iloilo, monopolizes the bank-note circulation of the Philippines, amounting to 2,407,560 pesos (a peso = 50 cents). Its capital is 1,500,000 pesos. The Hong Kong and Shanghai Banking Corporation has branches at Manila and Iloilo, and the Chartered Bank of India, Australia, and China at Manila and Cebú. The aggregate liabilities of all these establishments on December 31, 1901, was 53,415,809 pesos, including deposits of 35,012,127 pesos. The Savings Bank and Pawn Shop of Manila, capitalized at 221,460 pesos, had in January, 1902, deposits amounting to 755,829 pesos and total resources of 1,096,597 pesos.

FINANCE. The central government is supported chiefly by import and export duties. The provincial and municipal governments derive their support from internal taxes. The revenues and expenditures in the archipelago from the date of the American occupation, August 20, 1898, to the end of the fiscal year, June 30, 1901, were as follows:

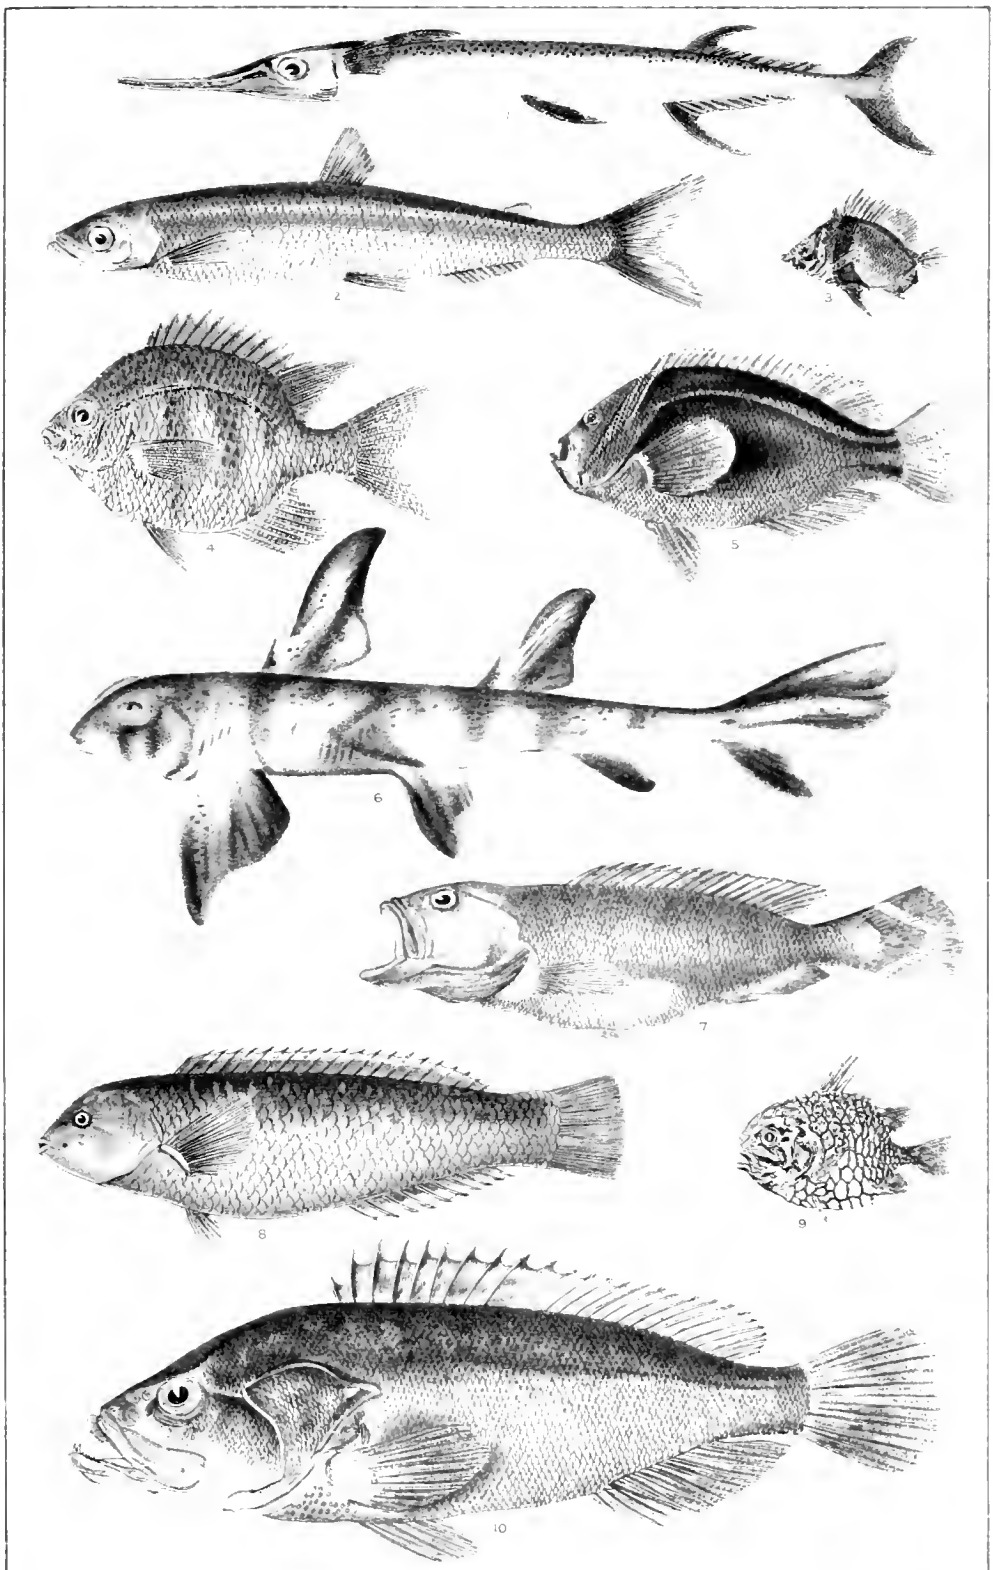
REVENUES	1899	1900	1901	Total
Customs	$3,097,864	$5,535,952	$9,032,600	$17,666,417
Postal	42,954	104,282	121,559	268,796
Internal	240,378	522,509	932,484	1,695,372
Miscellaneous	130,131	361,195	591,017	1,082,344
Total	$3,511,327	$6,523,938	$10,677,660	$20,712,929
EXPENDITURES				
Customs	$29,177	$134,685	$280,815	$444,678
Postal	30,410	89,149	147,031	266,591
Other expenditures	2,337,810	4,994,545	6,335,975	13,668,331
Total	$2,397,397	$5,218,379	$6,763,821	$14,379,600

One-half of the internal revenue receipts in each province is turned over to the provincial treasury, and the remaining one-half to the municipalities of the province. A poll tax of $1 Mexican is levied upon each male person between eighteen and fifty-five years of age, one-half being paid into the treasury of the town where he lives and the remainder into the provincial treasury. The municipal council may license saloons and other business requiring police supervision. An ad valorem land tax is collected for the benefit of the provincial and municipal governments, the provincial board levying one-eighth of 1 per cent. on the assessable land for roads and bridges, and may levy two-eighths more for general purposes. The municipal council is required to levy one-fourth of 1 per cent. for schools, and may levy one-fourth per cent. more for general purposes.

WEIGHTS, MEASURES, AND MONEY. The coinage in use comprises the Mexican silver dollar, and silver peso and fractional currency coined at the Manila mint, which was established in 1902. A large amount of pesos coined at the Philadelphia mint are sent to the Philippines in 1903. The Philippines silver coins are legal tender to the amount of $10. Two pesos are exchanged for $1 of United States money, and a ratio of 2 to 1 is maintained between Mexican dollars and United States gold. The metrical system of weights and measures is officially in use, but the Spanish denominations are also employed.

POPULATION. A census of the Philippines was

FISHES OF THE PHILIPPINES



JULIUS BIEN & CO. LITH. N.Y.

1 GREAT GAR - (BELONE GIGANTEA)
2 SMELT - (OSMERUS JAPONICUS)
3 FLAG - FISH - (HENIOCHUS MACROLEPIDOTUS)
4 A DEMOISELLE - (GLYPHIDODON SMARAGINUS)
5 AMPHIPNION FRENATUS
6 PORT JACKSON SHARK - (CESTRACION PHILIPPI)
7 A GROUPER - (SERRANUS URODELUS)
8 FOUR-COLORED WRASSE-(JULUS QUADRICOLOR)
9 CONE-FISH-(MONOCENTRIS JAPONICUS)
10 A SEA-BASS (SERRANUS MARGINALIS)

in Congress when the insurrection began in 1896, and the American authorities found returns for over two-fifths of the population stored in Manila. The returns were made the basis for the estimate of the population in the twelfth census of the United States, where it is given as 6,961,339. A later Government estimate is 6,975,073, with 1137 towns, the population being divided among the island groups as follows:

GROUPS	Area *sq. miles*	Population	Towns
Luzon	44,235	3,727,488	570
Marinduque	681	48,000	6
Mindanao	46,721	495,650	130
Mindoro	4,108	106,200	19
Palawan	5,037	52,550	14
Sulu Archipelago	1,029	22,630	14
Visayan Islands	25,302	2,495,908	381
Unassigned	740	24,858	3
Total	127,853	6,975,073	1,137

With the exception of Manila, the capital, which has a population of 350,000, there are no cities in the archipelago with more than 40,000 inhabitants, though there are about 30 towns with populations between 20,000 and 40,000. The most important of these are Albay, Batangas, Banan, Laoag, Lipa, and Taal in Luzon, Cebú in the Visayas, and Zamboanga in Mindanao.

EDUCATION. There is considerable controversy as to the exact status and results of the system of education in operation before the American occupation. It is contended, on one hand, that the provisions for primary and secondary education were largely neglected, the tendency being to centre efforts upon the few who were sent to the college or university. It is accordingly asserted that comparatively few persons stood out prominently as educated Filipinos, while the great mass were either wholly illiterate or could barely read and write. Other authorities maintain that the Spanish system, considering the conditions which existed, achieved fair results. The report of the United States Commissioner of Education states that "the public elementary school system required by the Spanish law, whatever its defects, was widely diffused over the archipelago when the Americans arrived." In some places the average of those who could read and write was high, in others low—a diversity due to local conditions. Higher education was well provided for, and presented many admirable features. Since September 1, 1900, the civil administration has put in force an educational bill designed to provide wider instruction for the masses as well as the more prosperous class. The archipelago has been divided into seventeen educational divisions, with an American superintendent over each division. Up to 1903 about 1000 American teachers had been distributed for primary work in the towns; 200 American teachers for secondary work were also assigned to duty; 200 soldier-teachers were detailed from their regiments; and 3400 Filipino teachers were also appointed. Instruction in the English language was provided in 1500 schools, in which more than 200,000 children were enrolled. Night schools were opened in various parts of the archipelago, with an enrollment of about 25,000 pupils. Grammar and high schools are a part of the system. Permanent normal schools and vacation normal courses for the training of Filipino teachers were organized. In 1903 plans were under discussion for increasing the number of trade schools and establishing schools of painting, sculpture, drawing, and music, and also a university at Manila. The aim of the common schools is in part to fit the Filipinos for practical work and to make a feature of agricultural and industrial training.

RELIGION. Under the treaty of peace of December 10, 1898, religious freedom is guaranteed to all. The people of the islands are largely Roman Catholic, though there are moon-worshipers, Mohammedans, Buddhists, etc. The Moros, living in the south, and the pagan wild tribes of the mountains, are the leading non-Christian classes. As shown by the Church registry in 1898, 6,559,998 Roman Catholics were distributed among 746 regular parishes, 105 mission parishes, and 116 missions. Most of the parishes are administered by Spanish friars of the Dominican, Franciscan, and Augustinian Orders, assisted by many native priests in the small parishes and missions, though since the American occupation several priests from the United States have been appointed to bishoprics. Controversy exists here also in regard to the attitude of the native population toward the friars. Some assert that they are obnoxious to a large part of the people, owing to the onerous contributions they are said to have levied for the support of the Church, and the large areas of tillable land they acquired, much of it, it is asserted, by dispossessing the owners on the pretext of exacting the Church's dues. The apologists of the friars, on the other hand, vigorously assert that their unpopularity is only with a faction of the natives, and springs largely from political motives. They call attention to the fact that a counter-movement of popular origin and considerable proportions has taken place in favor of the friars. When Spanish sovereignty ceased, many members of the Orders retired to Spain, and the policy of acquiring their lands and delegating their powers to other officials of the Church has been advocated in reports of the Philippine Commission.

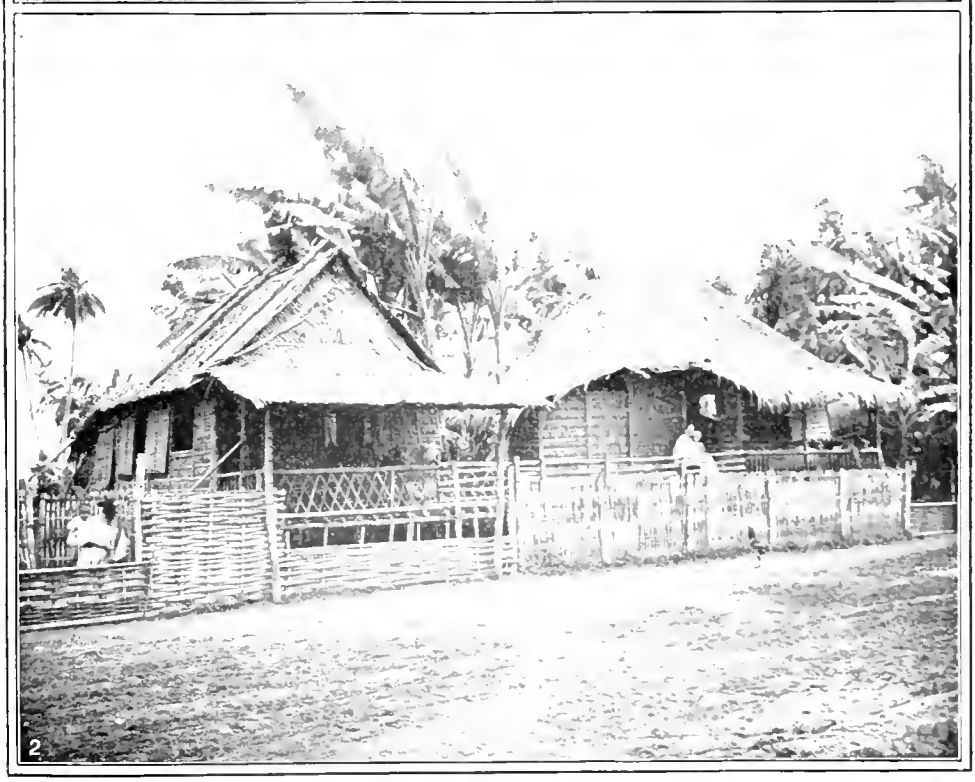
GOVERNMENT. For a time after the transfer of the Philippines to American control, the islands were held under military government subject to the orders of the President of the United States. In January, 1899, a commission was appointed by the President to investigate conditions in the Philippines. (See below under HISTORY.) In February, 1900, the provisional government of the islands was intrusted to a new board of civil commissioners, five in number, at the head of which was Judge William H. Taft of Ohio. The other members were D. C. Worcester, Luke E. Wright, Henry C. Ide, and Bernard Moses. The commission reorganized the local civil governments and in January, 1901, established a municipal code for the government of cities other than Manila and tribal settlements. An electoral system making the qualifications for suffrage the ownership of property, payment of certain taxes, or a knowledge of English or Spanish was also created. A constitution for the government of the provinces enacted by the commission provided that their officials should be a governor elected by the municipalities subject to the approval of the commission, and a secretary, a treasurer, a commissioner of public works, and a public prosecutor, all appointed by

the commission. From time to time the commission instituted civil governments in the localities as circumstances required, until in 1903 more than 700 localities had local governments suited to their conditions. In June, 1901, the civil and military administration of the islands were separated by the appointment of Judge Taft as civil governor, thereby relieving the military governor of his civil duties in the pacified provinces. Shortly thereafter the commission was increased from 5 to 8 by the addition of three natives and was reorganized so as to place each member at the head of an administrative department. By an act of the commission dated June 11, 1901, the judicial system was reorganized. A Supreme Court was created to consist of seven justices, four American and three native; and sixteen Courts of First Instance, over which natives presided, were established. A considerable portion of the minor criminal jurisdiction was transferred to justices of the peace. A new code of civil procedure, authorizing the use of either English or Spanish in judicial proceedings, went into effect September 1, 1901. The city of Manila, the capital, is governed by a board of three commissioners somewhat after the manner in which the city of Washington is governed. In addition to the above measures the present constitution of government for the Philippines consists of the order of April 7, 1900, creating the Philippine Commission and defining its powers; that of June 21, 1901, creating the offices of Governor and Vice-Governor; an act of the Philippine Commission of September 6, 1901, organizing the departments of the interior, of commerce and police, of finance and justice, and of public instruction; and the important act of July 1, 1902, for the temporary government of the Philippines, which continued the government established under the above-mentioned orders and acts.

The act of July 1, 1902, defined the citizenship of the Philippines as including all the inhabitants of the islands who were citizens of Spain at the date of the ratification of the treaty with Spain, February 6, 1899, and declared that as such they should be entitled to the protection of the United States. The substance of the bill of rights of the Federal Constitution, except the right of maintaining a militia and the right of trial by jury, was extended to the Philippines. The act directed the President of the United States to have a census of the islands taken, and within two years thereafter, if peace prevailed in the islands, a legislative assembly should be called into existence. This body is to consist of two chambers, the Philippine Commission constituting the upper one, while the Lower House is to consist of from fifty to one hundred popularly elected delegates apportioned among the provinces on the basis of population, except that each province shall be entitled to at least one member. Persons qualified to vote for delegates include those who have held office under the Spanish régime or who own property of the value of $250 or pay taxes amounting to $15 or over, or who speak, read, and write Spanish or English. Two resident commissioners to the United States are to be chosen by the Legislature, and both commissioners and delegates are to be chosen biennially. The Legislature is to hold annual sessions; but if at any session the Legislature refuses to vote the moneys or supplies for the support of the Government, the executive may appropriate sums equal to the amount last appropriated.

The Supreme Court, the Courts of First Instance, and the Municipal Courts as established by order of the Philippine Commission June 11, 1901, are continued. The United States Supreme Court is given appellate jurisdiction over all judgments of the Philippine Supreme Court in cases involving more than $25,000, or whenever the Constitution, the laws, or any right or title claimed under the authority of the United States is drawn in question. The Governor, Vice-Governor, members of the Philippine Commission, heads of executive departments, and the justices of the Insular Supreme Court are to be appointed by the President of the United States, with the advice and consent of the Senate. Congress reserves the power to annul all laws passed by the Philippine Legislature, and the Philippine Commission is directed to make annual reports of all receipts and expenditures to the Secretary of War. The Division of Insular Affairs instituted by the War Department is continued as the Bureau of Insular Affairs, and to this bureau are committed all matters pertaining to civil government in the insular possessions of the United States subject to the jurisdiction of the War Department. By a proclamation of July 4, 1902, the President of the United States declared the Philippine insurrection at an end everywhere except in the Moro territory and abolished the office of military governor, his authority in civil matters being superseded by that of the Philippine Commission.

Ethnology and Customs. The inhabitants are unequally divided between blacks, browns, yellows, and whites, and there is also a slight representation of reds. The blacks comprise native tribes, with descendants of African negroes and Papuans introduced by Spaniards. The native blacks are of Negrito type, commonly called Aeta, from a principal tribe; they are dwarfish in stature, and dwell in remote parts of the archipelago. They are usually regarded as the aborigines, and as remnants of a pigmy race; some students consider them degraded Papuans. There are only twenty thousand of them. The brown race, either pure or mixed, constitutes nine-tenths of the population. A fraction are related to the Polynesians; yet the distinctness of this type is problematical, and the ethnologist finds his surest identities in the vast numbers of Malay peoples in the islands. The first immigrants were uncultured savages, whose descendants are now represented in the interior and the outskirts of the islands by living tribes. These were followed by incursions in historic times of Malay peoples having alphabets and a primitive culture. About B.C. 200 came the ancestors of many head-hunting tribes. The immigration of the Tagal, Visaya, Vicol, Ilocano, and other industrial tribes is assigned to A.D. 100-500. Third and last came the Islamitic or Moro invasion, occurring in the fourteenth and fifteenth centuries of our era, and brought to an end by Spanish conquest in the sixteenth century. At present the brown Malay is mixing with white and yellow peoples. The yellow or Mongoloid type exists in the Philippines partly as pure-blooded Chinese, Japanese, Siamese, and Cambodians, but principally in mixtures of various sorts. The Chinese held sway in Luzon for centuries, and after their rule was thrown off trade continued between them and the natives.



STREET SCENES IN THE PHILIPPINE ISLANDS

1. MALASIQUI 2. SAN CARLOS

It is improbable that these immigrations and blendings were numerous prior to the founding of Manila (1571) and the coming of Mexican and Peruvian silver in trade. So vigorous was the Chinese invasion afterwards that it threatened to overthrow the Spanish rule, while it resulted in the creation of a large mestizo population. The red or American race found its way into the islands on the Spanish ships sailing annually between Acapulco and Manila in the sixteenth, seventeenth, and eighteenth centuries. It was not so much a migration of peoples as of arts. There are evidences of small settlements of Mexican Indians in and about Luzon, and the civilized portions of the archipelago were enriched by maize, pineapples, tobacco, cacti, agaves, and the varied industries associated with them. The white race, in all its important elements, Hamitic, Semitic, and Aryan, was permanently mingled with the brown during the 250 years of Spanish domination. In Northern Luzon and in the mountainous and central portions of other islands the native blood has not been changed, but elsewhere the term 'pure-blood' has little meaning. This blending has been most rapid in the Tagal, Vicol, and Visaya tribes, which constitute the largest fraction of the population.

The Negritos are small in stature, with closely curled hair, yellow sclerotic coat, and white teeth, which they file. They are among the shortest of mankind, the average stature being 1.47 meters (58 inches). Their cranial capacity is 1100 to 1200 cubic centimeters, and their cranial index 85. The Malay or brown Filipinos are of dark chocolate color and average 1.50 meters (59 inches) in stature. Some are meagre in body, but most of them are sturdy.

Culture among the Filipinos extends from the low savagery of the Negrito tribes to a form of civilization fairly comparable with that of the countries on the continent adjacent. The industrial life of the Filipinos is partly agricultural and mechanical, partly maritime. The outrigger canoe is in evidence about all the islands. Clothing is little needed as a defense against cold, but the need of protection from the sun's rays and the rain has quickened inventive faculty in devising a style of headgear which combines the functions of hat and umbrella, varying from island to island, with a rain cloak, also varying in form and material. The dwellings are made of bamboo, rattan, and palm leaves. The original fire-making device was the fire-saw, consisting of a section of bamboo stem, notched and laid on the ground and rubbed crosswise by another piece in shape like a knife; the bamboo fire syringe is also common.

Industrially the Filipinos are in the Iron Age. They have little machinery. All their tools are of the rudest sort, and are either Malay or Spanish. Many of them, especially the Moro tribes, work cleverly in metals, but do little at mining or reduction of ores. Their most elaborate work is done on the blades of edged weapons. Pottery is made by the brown peoples for domestic purposes; working in hard woods is a fine art, and in textiles the Filipinos excel. They split the bamboo and rattan into delicate filaments for hats and screens; make thread, twine, and rope of the native hemp; ornament their clothing and furniture with delicate vines and grasses; and weave the finest of cloth from the fibre of the pineapple. These fabrics are plaited by hand or wrought on looms, but it is difficult to tell which processes are Malayan and which came through Hispano-Mexican influences. The more advanced tribes rear a variety of small horse that is tough and serviceable; but the chief domestic animal is the carabao or water buffalo, which is largely used for turning water wheels for irrigation and as a draught-animal for plowing or hauling. Native transportation was originally by means of the buffalo, and rude water craft. Even before the coming of the Spaniards, the Chinese and the Japanese carried on a brisk trade with Manila and introduced their vehicles and money. During the 250 years of Spanish domination the 'groaning cart' and old-style water craft partly took the place of native devices.

The Negrito weapons of war and the chase are the bow with string of bamboo, and arrows with heads of wood or of iron procured in trade. The brown peoples have inherited from their ancestors edged weapons set on a hilt or a shaft. They carry also wooden shields, decorated with patterns cut in and rubbed with lime wash or mud. Firearms of many patterns are to be found. Fortification of the village is effected by path splinters and spiked pitfalls.

Fine art among the Filipinos had no separate existence, but the possession of a strong artistic sense is revealed by the taste displayed in their industries. Even the Negritos are not devoid of it. The dress of men and women; the metal working of the men, especially on their weapons; the exquisite textile work of the women all show artistic instinct. Under the influence of Spanish teaching and the inspiration of European and Christian motifs, some of the native Filipinos have attained distinction in painting and literature.

The principal tribes and languages are: Abaca, Abra Igorrote, Abulone, Adang, Aeta, Agutaino, Altaban, Apayao, Aripa, Atá, Bagobo, Baluga, Bangot, Barangan, Batak, Batane, Bicol, or Vicol, Bilane or Vilane, Bisaya or Visaya, Bonayanan, Buhuano, Bulalacaano, Bukidno, Bukil, Buquitnon, Cagayan, Calangan, Calaunian, Calana, Calinga, Caraga, Carolano, Catalangan, Catubangan, Cimarron, Coyuvo, Culáman, Dadayag, Dulangan, Dumagate, Durugnun, Eta, Gaddane, Gamungan, Guianga, Guimbahano, Guinaane, Halaya, Biligunyna, Hilloona, Ibalone, Ibanag, Ibilao, Ifugao, Igorrote, Hamut, Ilanos, Ilocanos, Hongote, Iraya, Isinay, Ita, Itaa, Italone, Itanega, Itetapane, Kiangane, Lutanga, Lutayo, Maguindanao, Malanee, Malanao, Mamámua, Mandaya, Mangnanga, Mangniane, Manobo, Mayoyao, Moro, Mundo, Nabaynngan, Negrito, Palanan, Pampango, Pangasinan, Quiangan, Sámale, Sameaca, Sangley, Sanguile, Silipan, Subano, Tagabaloye, Tagabawa, Tagabelie, Tagacaolo, Tagala, Tagbanua, Tandolano, Tinguian, Tinitian, Tino, Tirnray, Vico (Bicol), Vilane, Visaya (Bisaya), Zambale. Some of these names are also applied to localities, in which case the people may be called after the place, which is rare, or they may have given designation to the place, which is common. The more important tribes and languages are defined in their several places.

HISTORY.

In accordance with the terms of the Demarcation Bull of Pope Alexander VI. of May 4, 1493, the Spaniards were to make discoveries and to establish colonies beyond a meridian line in the Atlantic 100 leagues west of the Azores (later by

the Treaty of Tordesillas, June 7, 1494, 370 leagues west of the Cape Verde Islands), while the Portuguese were to confine their efforts to the field of discovery east of that line. In the race for the control of the spice trade of the East Indies the Portuguese came off victorious, for they reached the Moluccas or Spice Islands the year before Balboa discovered the Pacific Ocean, revealing that the Spaniards had found, not the Indies, but a great barrier continent that blocked the way thither.

The Moluccas lay so far to the east of India as to make it probable that if the demarcation line were extended round the earth they would be found to be in the Spanish half of the globe. It was to demonstrate this hypothesis and carry to completion the great design of Columbus to find a western route to the Spice Islands that Magellan undertook his voyage around America and across the Pacific. In March, 1521, he discovered a group of islands which he named after Saint Lazarus, whose festival was celebrated early in his stay among them. A few weeks later the heroic navigator lost his life in a skirmish with the natives. That he had achieved his project and proved that the Spice Islands lay within the Spanish half of the world was accepted by King Charles of Spain, but the impossibility of accurately determining longitude in those days, the difficulties of the voyage through the Straits of Magellan and across the Pacific, and financial necessities led him to relinquish all claims to sail or trade west of a new demarcation line, in the Antipodes, 297 leagues east of the Moluccas. (Treaty of Saragossa, 1529.) This really surrendered all rights to the newly discovered Islands of Saint Lazarus, which were slightly to the west of the Moluccas. The conquest of Mexico and the establishment there of the prosperous Viceroyalty of New Spain removed the difficulties presented by the navigation of the Straits of Magellan, and, in contravention of the provisions of the treaty, an expedition was dispatched to the islands in 1542 under the command of Villalobos. This expedition had no permanent result beyond giving to the group the name of 'Islas Felipinas,' in honor of the Prince, later King Philip II. The permanent conquest of the islands was achieved under Legaspi at the head of an expedition fitted out in Mexico. Legaspi arrived at Cebú in April, 1565. It was three years before his first reinforcements came, and five years before the conquest of Luzon was undertaken. In June, 1571, the city of Manila was founded, and this became the seat of the Spanish power. Within the next year great progress was made and at the time of Legaspi's death in August, 1572, the Spanish authority was securely planted in the islands and the conversion of the natives considerably advanced. Legaspi's force was small and the conquest was accompanied by relatively little bloodshed. The lack of social and political cohesion among the natives, the weakness of their religious beliefs, and the rivalries and hostility of the local chieftains opened the way for a patient and tactful prosecution of the policy of divide and rule; one chief after another was won over to the Spaniards, the picturesque ceremonials of the Church appealed to the artistic sense of the people, and the simple clan like social organization was skillfully utilized by the Spaniards as the basis of their rule. Lying on the extreme verge of the vast empire of Spain, the islands were commonly known as the Western Islands (Islas del Poniente), and until December 31, 1844, they were reckoned, so far as the calendar was concerned, in the Western Hemisphere, Manila time being about sixteen hours slower than Madrid time. The Portuguese protested against this invasion of their East Indian realm, but the conquest of Portugal by Spain in 1580 settled the question before there had been any serious collision. More formidable than the hostility of Portugal or the resistance of the natives were the incursions of Chinese pirates and later the attacks by the Dutch, who during their great contest with Spain made their way to the Indian seas and took possession of the Spice Islands.

The dominating impulse in this remote extension of Spanish power had been religious rather than commercial. The new conquest was to be an outpost of Christianity facing the great Asiatic heathen world. From it as a base the missionaries could prosecute their labors effectively in China and Japan. Religious purposes and interests continued to dominate the life of the islands for over three centuries. They never were in the true sense of the term a Spanish colony, but a great mission like the more familiar Jesuit missions in Paraguay and California. It is as a mission that the history of Spanish rule should be studied and its results estimated. To convert the natives, to collect them in villages where they would live under the oversight of the pastor with the faithful obedience of the flock to the shepherd and prepare themselves for salvation, was the simple ideal of the mission. That it was in a large measure achieved is the very general testimony of fairly dispassionate observers. The Christian population steadily increased, and the requirements of religion, while rigorously enforced, were not more burdensome than in Europe. There was little real oppression and hardly any exploitation of the people. Plantation slavery, the dark page in West Indian colonization, never existed. Schools were provided in the pueblos and in the larger towns hospitals and colleges; the native languages were given literary form, grammars and dictionaries were compiled and translations made of the simpler literature of the devotional life. The Christian population of the islands formed a unique community, the only large body of Asiatics permanently converted to Christianity in modern times. In its general framework the administration of the islands as a Spanish dependency was modeled on the system introduced into America, which in turn was an adaptation of that existing in the provinces of Spain. At the head was the Governor with viceregal powers, having by his side the Audiencia or Supreme Court. This body served not only as the highest court of appeal, but also as a check upon the arbitrary authority of the Governor. Another important restraint upon that official was the *residencia*, or obligation to stand ready to answer all charges of misbehavior which should be preferred during a period of six months, after the termination of his tenure of office. The heads of the provincial administration were the *Alcaldes Mayores*, whose functions were both executive and judicial. In his judicial duties the Alcalde Mayor was assisted by an assessor and a notary. The administrative division below the province was the pueblo or village, which was ruled by the Petty Governor, who was origi-

nally elected by the general suffrage of the married inhabitants of the pueblo, but in later years was chosen by a small body of thirteen electors. Within the pueblos the population was subdivided into little clan-like groups of forty or fifty families called barangays, a survival of the earlier native organization, each under a barangay headman (*cabeza de barangay*). Each family was assessed a tribute of 10 reals, about $1.25, and the headmen were responsible for its collection. The petty governors and headmen of barangays were Filipinos; the higher administrative officers were Spaniards. The inhabitants of these pueblos were all natives. No Spaniards were allowed to live in these mission villages except the friars, who exercised there the firm but ordinarily gentle sway of the parent or schoolmaster. In the few Spanish towns there existed the ordinary municipal organizations that prevailed in Spanish America. There was the town corporation 'el Cabildo' (chapter), consisting of two alcaldes (justices), eight regidores (aldermen), a registrar, and a constable. The members of the Cabildo held office permanently. Membership could be bought and sold or inherited.

At the head of the ecclesiastical administration stood the Archbishop of Manila, the Bishops of Cebú, Segovia, and Cáceres, and the Provincials of the four great Orders of friars (the Dominicans, Augustinians, Franciscans, and barefooted Franciscans), and of the Jesuits. The members of these Orders (the regular clergy) greatly preponderated in numbers and influence over the secular clergy, who were mostly natives.

The economic development of the islands was rendered impossible by the manufacturers in Spain, who demanded protection against Asiatic competition in the markets of Mexico and Peru, and secured the restriction of the imports from the Philippines to the cargo of an annual ship. Under this handicap the islands never were a self-supporting, much less an income-yielding, dependency. They were always a burden upon the treasury of New Spain. Their principal trade was with China and was in the hands of the Chinese. The vast majority of the pueblos were simple self-supporting communities of farmers and small artisans.

Secluded from the outside world, the domestic history of the Philippines is distinctively parochial in its character. There is little progressive political or economic evolution from generation to generation. Progress is manifested by the extension of the missions and the amelioration of the life of the natives. Much of the internal history is made up of the various conflicts between the clergy and the political administration or between the Archbishop and the friars. The chief incidents in external history are the volcanic eruptions, the incursions of the Chinese or Moro pirates, the attacks of the Dutch, etc. The events of the great Seven Years' War rudely interrupted this placid life. Spain, drawn into the maelstrom of this conflict in the vain hope of recovering Gibraltar, lost the Floridas and saw Havana and Manila fall before English fleets. The preliminaries of peace, however, had been agreed upon before the news reached England of the capture of Manila, and the conquest was therefore relinquished to Spain. The reforming Government of Charles III. exerted its activities even to the remote Philippines. The Royal Philippine Company was chartered to carry on direct trade between Spain and the islands (1785). Three years earlier the enterprising Governor-General Basco y Vargas, to make the colony self-supporting, introduced the Government tobacco monopoly (1782), by which lands suitable for growing tobacco were arbitrarily pressed into that service and the cultivators compelled by forced labor to produce stipulated amounts to be sold to the Government at fixed prices. This system of compulsory labor was practically the first attempt really to exploit the resources of the islands, and during the following century was fruitful in abuses and of the seeds of revolt. It was abolished in 1882. In this connection should be mentioned the *polos y servicios*, forty days' required labor on the roads, bridges, public buildings, etc., which was exacted of the natives in addition to their tribute. These requirements for public service could be canceled for from one to three dollars. The official class men were exempt from this burden.

The Mexican Revolution severed the ancient connection of New Spain with the 'Western Islands,' and the Spanish Constitution of 1812, which embodied the principles of the French Revolution, and which put all parts of the Spanish Empire on an equality and admitted the Philippines to representation in the Cortes, led the natives to believe that now they would be exempt from tribute and *polos y servicios*. Consequently, when the news came that Ferdinand VII. in 1814 had abolished the Constitution of 1812, the Ilocanos rose in rebellion. Henceforward the agitations of home politics and the example of the Spanish-American States steadily undermined the old-time stability of conditions in the Philippines. The mission system could not be maintained in its integrity. The number of Spaniards in the islands increased, the spirit of colonial exploitation grew, the monastic Orders which combined the functions of landlords and spiritual guides were more and more pervaded with the mercantile spirit. Nor did their predominant influence in the government of the islands at all diminish in an age progressively hostile to clerical control. The opening of the Suez Canal brought the Philippines relatively near to Europe and more than ever exposed them to the contending forces of modern thought. Promising young Filipinos completed their education in Europe. By a few weeks' voyage they found themselves in many respects transported from the sixteenth century to the nineteenth. That they should contentedly return to the earlier age was impossible. The Spaniards did not weather the transition. The final collapse began with the insurrection of 1896, which was primarily an agrarian revolt aimed at the expulsion of the Orders from their estates and the islands.

It seems to be agreed that the establishment of Masonic lodges in the islands and the admission to them later of prominent Filipinos and Mestizos of anti-clerical or liberal sentiments offered a nucleus for agitation, facilitated united action, and led immediately to the formation of the patriotic Asociación Hispano-Filipina, the Liga Filipina, and the revolutionary society, "el Katipunan." The first Masonic lodges were founded about 1860, but it was over a quarter of a century before they became active centres of anti-clerical agitation. The Asociación Hispano-Filipina was devoted to promoting Filipino national aspirations through literary channels, and established an organ, *La Solidaridad*, in Barcelona.

The Liga Filipina was founded by Dr. José Rizal (q.v.) to work for the expulsion of the friars and to secure the same political concessions for the islands that had been granted to Cuba, a larger recognition of the natives in the appointments to civil offices, and freedom of the press and of association. More radical than these was the Katipunan, which was established in 1892 to secure independence by open revolt, and began by wholesale assassinations of Spanish officials and friars. The existence of an elaborate plot was revealed by a native, August 19, 1896, and on the 25th the mask was entirely thrown off. The garrison of Manila consisted of only 300 Spanish regulars and about 1200 native soldiers. The total number of Spanish soldiers in the islands was under 2000. The authorities could act only on the defensive until October, when reinforcements began to arrive from Spain. On the other hand, the insurrectionists were hampered by a great lack of arms and ammunition. The insurrection centred in the province of Cavité, which was under the control of the rebels until their power was broken in the spring of 1897 by the vigorous campaign of General Lachambre. Its leaders were Andrés Bonifacio, the head of the Katipunan, and Emilio Aguinaldo (q.v.).

After organized resistance had been shattered, it seemed wise to the Governor-General, Primo de Rivera, to attempt to secure peace by obtaining the withdrawal of the native leaders from the islands. In accordance with the Treaty of Biacnabató, Aguinaldo and some of the other generals withdrew to Hong Kong. No properly authenticated text of this treaty has ever been published. That made public by Aguinaldo is substantially identical with the demands which he made, and which it would appear were not acceded to by Primo de Rivera. Aguinaldo demanded $3,000,000, the expulsion of the friars, the representation of the Philippines in the Cortes, equality of Filipino and Spaniard in the administration of justice, the participation of Filipinos in the higher administrative offices, a readjustment of the property of the parishes and of the taxes in favor of the natives, the proclamation of the individual rights of the natives, and liberty of association and of the press. Aguinaldo has asserted that the suppression of the religious Orders and the establishment of administrative autonomy were agreed upon, although not put down in writing, Governor-General Primo de Rivera giving his word of honor that the agreement would be fulfilled. Primo de Rivera, on the other hand, maintained that nothing but money and personal security were promised to the leaders. The treaty was signed December 17, 1897. Only the first instalment (£400,000) of the sum of $800,000 finally fixed was ever paid, and, on the other hand, the insurrection was quieted only temporarily. In March, 1898, a new rising in the provinces north of Manila took place and early in April there was an outbreak in the island of Cebú. On March 24th the Seventy-fourth Regiment of native soldiers deserted to the insurgents, who now vastly outnumbered the Spanish forces, but were greatly hampered by the lack of arms.

The day that war began between Spain and the United States, Aguinaldo appeared in Singapore, and on April 24, 1898, United States Consul-General Pratt had a conference with him in reference to coöperating with Commodore Dewey. Of the exact nature of the understanding the same uncertainty exists as in the case of the Treaty of Biacnabató. What is certain is that Commodore Dewey arranged for Aguinaldo to follow him to Manila and that Aguinaldo expected the United States to pursue in the Philippines the policy proposed for Cuba, the policy of common action with the insurgents against Spain for their liberation from her rule. What is probable is that Consul Pratt at Singapore, and Consul Wildman at Hong Kong, and Commodore Dewey as well, had similar expectations. Later they all equally disclaimed having bound the United States in any way. On May 1st the Spanish fleet in the Bay of Manila was annihilated by the Asiatic Squadron under Commodore Dewey. Aguinaldo arrived at Cavité on May 19th, in the American dispatch boat *McCulloch*. He had an interview with Dewey, who supplied him with arms for the insurgents, who flocked to his standard. In the weeks that elapsed until the arrival of General Merritt late in July, Aguinaldo secured control of the Province of Cavité and thoroughly invested Manila by land. His capture of Spanish garrisons was not only sanctioned, but assisted by Dewey, and had it not been for the native forces the capture of Manila would have been a far more arduous undertaking for the Americans and the Spanish forces might have eluded them by retiring into the interior. As it was, the condition of the Spaniards was hopeless, and on August 11th the arrangement was effected, through the Belgian Consul André, by which the American ships should refrain from firing on the walled city of Manila and the Manila forts from firing on the ships, while on shore there should be only a brief show of resistance to enable the Spanish general to save honor at least. The American soldiers were in ignorance of this arrangement, and through an accident there was more bloodshed than was intended at the taking of the city (August 13th). To the onlooking foreigners in the harbor the transaction seemed like a travesty of war. The fall of Manila marked the complete collapse of the Spanish power in the islands. The Americans held the capital and controlled the harbor; and Aguinaldo and the insurgents rapidly extended their control over the various provinces.

In the meantime (almost exactly coincident with the capture of Manila) came the signing at Washington of the peace protocol (August 12th), providing that the United States should occupy and hold the city, bay, and harbor of Manila, pending the conclusion of a treaty of peace, which should determine the control, disposition, and government of the Philippines. On October 31st, after the Peace Commission had been at work in Paris for a month, the Spanish plenipotentiaries were painfully surprised by a demand for the cession of the whole group. It was nearly a month before Spain yielded to the inevitable. In the treaty as signed December 10, 1898, Spain ceded the whole group and the United States agreed to pay Spain $20,000,000, give Spanish ships and merchandise admission to the islands on the same terms accorded to American ships and goods for a period of ten years, and to transport to Spain the Spanish soldiers captured at the surrender of Manila. The treaty was submitted to the Senate of the United States January 4, 1899, and it was ratified February 6th, by only three votes more than the necessary two-thirds majority (57 to 27).

In the meantime, before the protocol of peace, Aguinaldo had organized a government (June 12, 1898), and in the provisional constitution promulgated June 23d he announced the independence of the islands as the chief object of the Revolutionary Government. On August 6th Aguinaldo appealed to the powers of the world for recognition of his forces as belligerents and of the independence of the Philippines, asserting that the Revolutionary Government was predominant in fifteen provinces. These provinces comprised the central part of Luzon and the majority of the inhabitants. During the following months the Americans held Manila and the native forces the rest of the island. The hopes of independence under American protection, which had been based upon the declared attitude of the United States toward Cuba and the friendly cooperation of Admiral Dewey and General Anderson, were rudely shaken by the proposed annexation of the islands to the United States, and relations became greatly strained in consequence of President McKinley's proclamation of December 21st that the islands were ceded to the United States and that military rule was to be extended over them as rapidly as possible. The tension proved too great to last, and on the night of February 4, 1899, hostilities broke out at Manila. The news of this battle, reported as an attack by the Filipinos on the Americans, no doubt contributed to the ratification of the peace treaty two days later.

The first intimations that the islands might be annexed called forth opposition in the United States, which was increased by the open declaration of that policy by the Government and greatly intensified by the outbreak of war between the American army and the Filipino republic. This opposition characterized the acquisition of the islands as the beginning of imperialism, as at variance with the traditional policy of the United States toward peoples struggling for independence, as being identical in its purposes with the projects of Napoleon III. in Mexico, as irreconcilable with the principles of the Declaration of Independence and the spirit of the Constitution, and as inevitably involving unknown expense and bloodshed. It was urged that our policy should have been one of conciliation and substantially identical with that pursued in Cuba, that the Filipinos were as capable of self-government as the South Americans, in whose behalf the Monroe Doctrine was first promulgated, or as the adherents of Juarez in Mexico, who were supported by the United States against Maximilian, and that a protectorate by the United States would have been acceptable to the Filipinos. On the other side, the acquisition of the islands by the United States was declared the only possible solution that would save them from anarchy or from falling into the hands of some European power, and that it was the duty of the United States to accept the burden. Others felt strongly the appeal of the great natural resources of the archipelago, almost undeveloped by Spain, and the immense strategic importance of holding them in view of the future Eastern Asiatic questions.

The discussion of the points of view and the policy of the Government were hampered by great lack of knowledge of the situation. To meet in part this difficulty, President McKinley appointed, in January, 1899, a commission, consisting of President Schurman of Cornell University, Admiral Dewey, Gen. E. S. Otis, the Hon. Charles Denby, and Prof. D. C. Worcester, to investigate conditions in the islands and to labor for the acceptance of American rule by the natives. In March, 1899, the Commission began its work. On April 5th it issued a proclamation to the people of the islands, explaining the purpose of their mission and the intentions of the American Government. The efforts of the Commission were devoted particularly to conciliating prominent Filipinos, and to building up a party favorable to American rule. To do this concurrently with the vigorous prosecution of the war was uphill work. In May they had a conference with some representatives of Aguinaldo, but it came to nothing.

The operations of the American army disorganized the republic and the national movement became embodied in the leadership of Aguinaldo. During the first nine months of the war disappointingly little headway was made by the Americans. The great majority of the engagements were within a radius of fifty miles of Manila. The military authorities exercised a rigid censorship over the press dispatches, so that it was practically impossible for the general public to know the real conditions. In the fall and winter of 1899 there was greater progress. Most of the country, from Manila to Dagupan, came under American control, and the native army was driven to the mountains. The principal events in 1900 and 1901 were in connection with the process of establishing civil government in the islands for which see above under *Government*.

On March 23, 1901, Aguinaldo was captured, and on July 4th military government was superseded by civil government in the pacified districts. By act of Congress, approved July 1, 1902, civil government was established throughout the islands. Up to the establishment of civil rule in July, 1902, the total number of troops sent to the islands amounted to 4135 officers and 123,903 men. The cost of the war to the United States was over $170,000,000.

BIBLIOGRAPHY. The numerous works on the Philippines fall naturally into two groups, those describing the condition of the islands under Spanish rule, and those dealing with the new order of things brought about by American supremacy. To the first group belong the following: Mallat, *Les Philippines* (Paris, 1846), perhaps the best single work; Jagor, *Reisen in den Philippinen* (Berlin, 1873); Sansianco, *El proceso de Filipinos, Estudios economicos, administrativos y politicos, Parte economica* (Madrid, 1881); Jordana y Morera, *Bosquejo geografico e historico-natural del archipielago filipino* (ib., 1885); Montero y Vidal, *El archipielago filipino y las islas Marianas, Carolinas y Palaos* (ib., 1886); id., *Historia general de Filipinas* (Madrid, 1887-1895), perhaps the best general history; Meyer and Schadenberg, *Die Philippinen* (Dresden, 1890-1892); Zuñiga, *Estadismo de las islas Filipinas*, ed. by Retana (Madrid, 1893), which has a bibliography; Sastrón, *Colonizacion de Filipinas* (Malabón, 1897). The second group includes: Foreman, *The Philippine Islands* (2d ed., London, 1899), which gives an immense amount of information, and is the basis of several other works; Youngbusband, *The Philippines and Round About* (New York, 1899), a general résumé of the history and political conditions; Lala, *The Philippine Islands*

(New York, 1899), which gives the point of view of a progressive Filipino; Sawyer, *The Inhabitants of the Philippines* (London, 1900), a historical study of the elements that make up the population of the islands; Buel, Wright, etc., *Our Late Wars: Spain and Our New Possessions* (Washington, 1900); Robinson, *The Philippines: The War and the People* (New York, 1901); Schurman, *Philippine Affairs: A Retrospect and an Outlook* (New York, 1902), an account of the proceedings of the first American Commission; *U. S. Philippine Commission, Report to the President* (4 vols., Washington, 1900-1901); Blair and Robertson, *Philippine Islands, 1493-1803*, an exhaustive work on the early history, compiled from original documents, to be in 55 vols. (Cleveland, Ohio, 1903 et seq). On special periods of the history, consult for conquest and first half century, A. de Morga, *The Philippine Islands*, trans., Hakluyt Society (London, 1868); for the eighteenth century, Le Gentil, *Voyage dans les mers de l'Inde* (Paris, 1781). For the first half of the nineteenth century, Comyn, *Memoria sobre el estado de Filipinas* (Madrid, 1820; Manila, 1877; trans. by Walton, London, 1821); Sinibaldo de Mas, *Informe sobre el Estado de las Islas Filipinas en 1842* (Madrid, 1842); Buzeta and Bravo, *Diccionario geográfico, estadístico, histórico de las Islas Filipinas* (Madrid, 1850); Bowring, *A Visit to the Philippine Islands* (London, 1859). The novels of José Rizal, the Filipino patriot, illustrate the social conditions prior to 1896. *Voli me Tangere* (Berlin, 1856) appears in English somewhat condensed in two editions— *An Eagle Flight* (New York, 1901), and *Friars and Filipinos*, trans. by Gannett (New York, 1902). It was translated into French as *Au pays des Moines* (Paris, 1899). Other works on miscellaneous subjects are: Semper, *Reisen im Archipel der Philippinen* (Leipzig, 1868-1901); Blumentritt, "Versuch einer Ethnographie der Philippinen," in *Petermanns Mitteilungen, Ergänzungsheft* 67 (Gotha, 1882); Worcester, *The Philippine Islands and Their People* (New York, 1898); Stevens, *Yesterdays in the Philippines* (London 1899); Tornow, "The Economic Condition of the Philippines," in *National Geographic Magazine*, vol. x. (Washington, 1899); Morris, *Our Island Empire* (Philadelphia, 1899); Millet, *The Expedition to the Philippines* (New York, 1899); Sonnichsen, *Ten Months a Captive Among Filipinos* (New York, 1901); and for bibliography, Josephson, "Bibliographies of the Philippine Islands," *Bulletin of Bibliography*, vol. ii. (Boston, 1899). For the ethnology, consult: Blumentritt, "List of the Native Tribes of the Philippines, etc.," in *Smithsonian Report* (Washington, 1901); Meyer, "Die Philippinen," in *Ethnographisches Museum*, vol. viii. (Dresden, 1890); Brinton, "The Peoples of the Philippines," *American Anthropologist*, vol. xi. (New York, 1898), which has a bibliography; Meyer and Schadenburg, *Album von Philippinen-Typen* (Dresden, 1891); id., "Die Philippinen," and id., "Negritos," *Königlich-Ethnographisches Museum zu Dresden* (Dresden, 1893).

PHILIPPINE LANGUAGES. The number of languages spoken in the Philippine Islands is variously estimated as from about 25 to over 50. These languages may be considered under two heads: (1) the languages of the Negritos, probably the remnants of the aboriginal population, who live in scattered tribes in the interior of most of the large islands; (2) the languages of the various tribes of Malay race which constitute the bulk of the population (Christian, Mohammedan, and pagan).

About the idioms of the Negritos very little is known, but they are apparently similar to the Malay dialects. This similarity, however, is perhaps to be explained as due to the influence of the languages of the surrounding Malay tribes, especially as, according to Spanish authorities, the Negrito languages are of monosyllabic structure, and entirely different from the languages of the Malays.

The idioms of the Malay tribes form a closely connected group of tongues which constitute a branch of the Malayo-Polynesian family of speech. The principal languages of the Christian tribes are: Batan (Batan and Babuyan islands, north of Luzon), Ibanag (North Luzon), Ilocan (Northwest Luzon), Pampango (Central Luzon), Pangasinan (West Luzon), Tino (language of the Zambals, West Luzon), Tagalog (Manila, Middle Luzon, coast of Mindoro), Bikol (South Luzon), Bisayan (spoken in various dialects in the Bisayan Islands, and North and East Mindanao). The principal languages of the Mohammedan tribes are the Sulu of the Sulu subarchipelago and the coasts of Palawan, and the Magindanao of Southwest Mindanao. The idioms of the pagan tribes which inhabit the mountain districts of Northern Luzon, a large part of Mindanao, and the interior of Mindoro, Palawan, and the western Bisayan Islands, are very numerous, but little known. Among the best known are the Gaddan and Isinay of Luzon, and the Tiruray and Bagobo of Mindanao. A number of the Philippine languages, such as Tagalog and Bisayan, have reached a high state of development, and are well suited for literary use.

The vocabularies of the Philippine languages contain several foreign elements. In common with other languages of the Malay branch of the Malayo-Polynesian family, many of the Philippine dialects have borrowed a number of Sanskrit words. The languages of the Christian tribes also contain a number of Spanish words, those of the Mohammedan tribes a number of Arabic words.

The alphabets in which the native languages were or are written are also due to these foreign influences. The native alphabets, which are no longer used except by the Mangians of Mindoro and the Taghanuas of Palawan, were probably derived from India. The Mohammedan tribes of the south now use the Arabic alphabet with some additional signs, while the languages of the Christian tribes are written in the Roman alphabet conformed to the peculiarities of Spanish orthography.

The sounds of the Philippine languages are in the main similar to those of English. All the languages, however, possess a peculiar guttural-nasal sound (written *ng̃*) distinct from the ordinary guttural-nasal *ng* as in Eng. *sing*. In some of the languages, as in Tagalog and Bisayan, there is a peculiar *r*-sound, due to a phonetic modification of *d*.

The roots of these languages are for the most part dissyllabic. They may be used uncombined as nouns or adverbs, but only rarely as verbs. Derivation is accomplished by means of a great variety of particles, which are usually employed as prefixes, though there are a few suffixes and infixes. So prominent a characteristic is this use

of particles, that these dialects are sometimes spoken of as 'Particular' languages. Reduplication is very common in the formative processes of both noun and verb. There is no distinction of gender, nor is there, generally speaking, any inflection to denote person, number, or case in verbs or nouns. Only in certain pronouns is there found a species of inflection to indicate case. Verbs are practically always derivative, the particles employed being of two kinds: (1) special verbal particles, which give the root a simple verbal meaning or the signification of causative, intensive, etc., each particle generally having two slightly different forms, one used with active and the other with passive verbs; (2) the common or essential passive particles, which are an essential part of practically all passive forms. The combination of root and verbal particle is often modified to indicate differences in mood and tense.

The most salient syntactical characteristics of these languages are: (1) the use of certain particles, so-called ligatures, to connect two or more words which stand to each other in the relation of modifier and modified; such as adjective and noun, noun or pronoun and appositive, adjective or verb and adverb; (2) the prevailing use of a passive construction, the verb standing in the active only when the object of the action is something indefinite or when the agent is specially emphasized; (3) a paucity of simple prepositions, one or two being used to express the greatest variety of relations.

The following is a brief grammatical sketch of Tagalog, the most important of the Philippine languages:

The articles are simply definite, personal, and inclusive (used with names of persons), as *ang táwo*, 'the man,' *si Pedro*, 'Peter,' *sinà Pedro*, 'Peter and his companions.' They have three case forms, nominative, genitive, and oblique. The plural of nouns is expressed by preceding *manǧá*, e.g. *manǧá táwo*, 'men;' case, by the case forms of the article or pronominal adjectives.

Adjectives are usually made by prefixing *ma* to a root, as *ma-bùti*, 'good;' plural *mabubùti or manǧá mabùti*.

The pronouns have usually three case forms. Among them are to be noted *tayo*, 'we (including you),' *kami*, 'we (not you),' *kita*, 'we two.'

The ideas of 'being' and 'having' are expressed by independent particles.

Verbs are divided into seventeen classes according to the special verbal particles. Four stems are distinguished, imperative-infinitive, future, preterite, and present. One class has no special particle in the passive, the active particle being *um;* in the others the special particle has generally initial *p* in the passive, which becomes *m* in the imperative-infinitive and future active, and *n* in the preterite and present active, as *pad, nag, nag*, etc. The present and future are characterized by reduplication. The common passive particles are *in, i, an*.

Practically the only simple prepositions are *sa* and, with names of persons, *kay* and *kanì*, 'to,' 'for,' 'from,' 'in,' etc. Adverbs and conjunctions are numerous and important.

The ligatures are, *-ng* after a vowel or *n*, *na* after other consonants, as *ang malakas na táwo*, 'the strong man,' *lubhà-ng mabùti*, 'very good.'

The construction of verbs is very similar to that of nouns. When the subject precedes, it is connected with its verb by the particle *ay*, 'to be.' The direct object of the active and the agent of the passive stand in the genitive, other nominal adjuncts in the oblique case. Any verbal form may take the article *ang*. The character of the subject determines the verbal form to be used in a sentence. In general, if the subject is the agent of an action, the verb stands in the active, otherwise in the passive. The *in*-passive is used in general when the subject is the object of an action, the *i*-passive when it is the object of an action away from the agent, or the cause of an action, the *an*-passive when it is the place of an action.

The Philippine languages possess little literature. The old native manuscripts inscribed on leaves or strips of cane have been lost. At the present day the scanty native literature may be grouped under three heads: (1) religious writings; (2) native poetry; (3) native newspapers and newspaper articles.

Consult: Totanes, *Arte de la lengua Tagala* (2d ed., Binondo, 1865); Campomanes, *Lecciones de gramatica Hispano-Tagala* (5th ed., Manila, 1894); Noceda, *Vocabulario de la lengua Tagala* (2d ed., ib., 1860); Zuñeo, *Metodo del Dr. Ollendorff . . . adaptado al Bisaya* (ib., 1871); Bermejo, *Arte compendiado de la lengua Cebuana* (Bisayan) (2d ed., Tambobong, 1894); Lozano, *Cursos de lengua Panayana* (Bisayan) (Manila, 1876); Mentrida-Aparicio, *Arte de la lengua Bisaya-Hiligayna* (Tambobong, 1894); Figueroa, *Arte del idioma Visaya de Samar y Leite* (2d ed., Binondo, 1872); Encarnacion, *Diccionario Bisaya-Español* (3d ed., Manila, 1885); Naves, *Gramatica Hispano-Ilocana* (2d ed., Tambobong, 1892); Agustín, *Vocabulario Iloco-Español* (2d ed., Manila, 1888); De Cuevas, *Arte nueva de la lengua Ybanag* (2d ed., ib., 1854); Bugarín, *Diccionario Ibanag-Español* (ib., 1854); Bergaño, *Arte de la lengua Pampanga* (2d ed., Sampaloc, 1736); id., *Vocabulario de la lengua Pampanga* (2d ed., Manila, 1860); Pelliser, *Arte de la lengua Pangasinana* (2d ed., ib., 1862); Cosgaya, *Diccionario Pangasinán-Español* (ib., 1865); San Agustín-Crespo, *Arte de la lengua Bicol* (ib., 1879); Cowie, *English-Sulu-Malay Vocabulary* (London, 1863); Juanmartí, *Gramatica de la lengua de Mindanao* (Manila, 1892); id., *Diccionario Moro-Maguindanao-Español* (ib., 1892).

PHILIPPONS. A Russian sect, a branch of the Raskolniki (q.v.), who emigrated to Lithuania and East Prussia at the beginning of the eighteenth century. They take their name from their leader, Philip Pustosviät. They are described as peaceable and orderly, skilled in agriculture, thrifty, and industrious. They refuse to take oaths or perform military service, and set a high value upon suffering and death for conscience' sake. Priestly duties, such as leading in worship, baptism, and absolution, are performed by the oldest of the community. They do not observe the Lord's Supper, and have no confirmation or religious marriage ceremony. Their religious services consist in singing psalms, and reading the Gospels.

PHILIPPOP'OLIS (Bulg. *Plovdiv*, Turk. *Filibeh*). The largest city of Bulgaria next to Sofia, and formerly the capital of Eastern Rumelia. It is situated in a wide, fertile plain at the head of navigation on the Maritza

River, on the railroad between Constantinople and Sofia, and 80 miles southeast of the latter city (Maps: Balkan Peninsula, E 3). Most of the houses are of wood, but the city has in recent years been much enlarged and beautified by the laying out of new streets and public parks, such as the beautiful Exhibition Park, laid out in 1892, and the growing up of fine residential suburbs containing the villas of wealthy Greeks and Bulgarians. The city is the seat of a Greek archbishop, and has a new Greek cathedral, besides a number of other Christian churches and many mosques. There are also a college and a national library. Philippopolis is the chief commercial centre of Southern Bulgaria, and has an active trade in the products of its manufactures, such as silk and cotton fabrics and attar of roses, as well as in rice, grain, tobacco, and hides. Population, in 1888, 33,032; in 1900, 42,849, of whom nearly half are Bulgarians, the remainder being mostly Turks and Greeks. Philippopolis was an important Thracian city in ancient times. It was almost wholly destroyed by an earthquake in 1818, and again by fire in 1846; but it recovered rapidly, owing to its excellent trade facilities.

PHILIPPOTEAUX, fē'lē'pō'tō', Félix (1815-84). A French battle painter. He was born in Paris, and was a pupil of Léon Cogniet. His thorough knowledge of military details enabled him to depict the turmoil of battle with great historical truth, as may be judged by the following more important productions from his brush: "Louis XV. Inspecting the Battlefield of Fontenoy" (1840, Luxembourg Museum); "Battle of Balaklava" (1859); and some in the Museum at Versailles, such as the "Battle of Rivoli" (1844); "Bayard on the Bridge of Tarigliano" (1563); "Battle on the Alma" (1875). His "Last Banquet of the Girondists" (1850, Marseilles Museum) is also worthy of notice. He is well known as a painter of panoramas, in which he made great improvements. (See Panorama.) He received a medal of the first class in 1840 and the cross of the Legion of Honor in 1846.

PHILIPPSBURG, fil'ips-bûrk. A town in the Grand Duchy of Baden, situated near the Rhine, about 17 miles north of Karlsruhe. It was once a noted fortress originally founded by the bishops of Speyer at the beginning of the seventeenth century. It played a conspicuous part in the wars of the seventeenth century, and the fortifications were destroyed in 1800. Population, in 1900, 2546.

PHILIPPSON, fil'ip-zŏn, Martin (1846—). A German historian, born at Magdeburg. He studied at Bonn and Berlin, became docent at Bonn in 1871, and in 1878 professor in the University of Brussels. From this post he resigned in 1890 after a sharp quarrel with the anti-German student body, and removed to Berlin. Philippson wrote: *Geschichte Heinrichs des Zweiten* (1874); *Heinrich IV. und Philipp III.* (1874-76); *Geschichte des preussischen Staatswesens vom Tode Friedrichs des Grossen bis zu den Freiheitskriegen* (1880-82); *Kurfürst Friedrich Wilhelm von Brandenburg* (1879-1901); *Kulturgeschichte Europas seit dem Untergange des Mittelalters* (1898); and *Das Leben Kaiser Friedrich III.* (1900).

PHIL'IPS, Ambrose (1675?-1749). An English poet, born in Shropshire, probably in 1675. He graduated from Saint John's College, Cambridge, B.A. in 1696, M.A. in 1700, and was elected fellow of his college, but he resigned his fellowship (1708) and traveled on the Continent. From Copenhagen he addressed (March 9, 1709) an *Epistle to the Earl of Dorset*, which was published in the *Tatler* (No. 12) with warm praise by Steele. The same year appeared his pastorals in Tonson's *Miscellany*, along with Pope's *Pastorals*. Then ensued a controversy as to which poet had better succeeded. Both series are artificial. Philips was angered by a mock commendation of his pastorals which Pope contributed to the *Guardian* (No. 40), and he is said to have hung up a rod at Button's coffee-house for ehastising his adversary. No encounter ever took place. Philips was, however, remembered in the *Dunciad*. In ridicule of Philips, Gay wrote the *Shepherd's Week* (1714), descriptive of rustic life with the gilt off. In 1712 Philips was lauded for his adaptation of Racine's *Andromaque*. In 1718-19 he edited an imitation of the *Spectator* called the *Freethinker*. His support of the Government led to his appointment as secretary to Bishop Boulter in Ireland (1724). He also represented Armagh in the Irish Parliament; was made secretary to the Lord Chancellor (1726), and judge of the Prerogative Court (1733). He died in London, June 18, 1749. Philips also translated the odes of Sappho (1713), once thought to be a brilliant achievement. Perhaps his best work is represented by his odes to children (1725-26). Consult: Pope's *Works*, ed. by Elwin and Courthope (10 vols., London, 1871-89); and Johnson's *Lives of the Poets*, ed. by Henley (London, 1896).

PHILIPS, Francis Charles (1849—). An English novelist and playwright. He was born at Brighton and educated for the army, but he left army life and in 1884 became a barrister. At that time he began, without ceasing to be a barrister, to write both plays and novels. Of the latter the most noted is *As In a Looking Glass* (1885), which was dramatized and played both by Mrs. Bernard Beere and by Sarah Bernhardt. Among his other books are: *A Lucky Young Woman* (1886); *The Dean and His Daughter* (1887), on which was founded the play of *The Dean's Daughter*, by himself and Sydney Grundy; *Young Mrs. Annesley's Courtship* (1890); *Mrs. Bouverie* (1894); *The Luckiest of Three* (1896); *Men, Women, and Things* (1898), etc. With various collaborators, he is the joint author of the plays *Husband and Wife*, *A Woman's Reason*, *Papa's Wife*, and others.

PHILIPS, or **PHILLIPS**, John (1676-1709). An English poet, born at Bampton, Oxfordshire, December 30, 1676, and educated at Winchester School and at Christ Church, Oxford. He died at Hereford, February 15, 1709. Philips is still known for two poems: the *Splendid Shilling*, a burlesque (1701), and *Cyder* (1708), on the plan of Vergil's *Georgics*. The first was translated into Latin, and the second into Italian. As a Tory reply to Addison's *Campaign*, Philips wrote *Blenheim* (1705). Philips was among the few poets between Milton and Thomson to cultivate blank verse. Consult Johnson's *Poets*, ed. by Henley (London, 1896).

PHILIPS, Katherine (1631-64). An English poet, better known by her literary nickname, 'the Matchless Orinda.' She was born in London,

the daughter of John Fowler, a well-to-do merchant. In 1647 she married a Welshman, Hector Philips, son of her mother's second husband; four years afterwards she addressed Henry Vaughan in what seems her first poem; and she soon formed that literary and friendly circle which included Jeremy Taylor and Sir Charles Cotterel, and in which she took the name Orinda. She spent the year 1662 in Dublin and there made many friends among the Royalist Party, with which she had sentimentally allied herself, and translated Corneille's *Pompée* with great success. *Horace* she did not live to complete, for she died of smallpox in her thirty-third year. Her poems, printed without authorization in 1663, were highly praised by her contemporaries. Her *Letters to Poliarchus* (Sir Charles Cotterel) were published in 1705. Consult Gosse, *Seventeenth Century Studies* (London, 1883).

PHILISTINES (Lat. *Philistini*, from Heb. *Pĕlishtī*, Philistine). The designation in the Bible of a people who lived on the coast of the Mediterranean, to the southwest of Judea, from Ekron toward the Egyptian frontier, with their eastern limit at Beth-Shemesh. Aside from a few notices in Assyrian and Egyptian inscriptions, we have no knowledge of the early history of the Philistines, except what may be gathered from the Old Testament, in which their relations to the Hebrews are set forth in the course of the historical narratives. The people called Philistines were immigrants who came into Canaan from Caphtor (probably Crete). They are probably identical with the *Plst* of the Egyptian inscriptions, who invaded Egypt from the north in the time of Rameses III. and, being repelled, settled on the Syrian coast. Their settlement in Western Palestine presents, therefore, a parallel to the Hebrew conquest of Canaan. In both cases the new comers dispossessed an older population, and adopted the language and to a large extent the customs of the conquered race. But, while the Hebrews and Canaanites belonged to the same Semitic stock, the Philistines are aliens in a racial sense. At the time of the Hebrew conquests, they were already in Palestine, and their five central cities, Ashdod, Gaza, Ashkelon, Gath, and Ekron, around which their history, as far as we know it, centres, were presumably already in existence. Hebrew tradition contains a reminiscence of an unsuccessful attempt to drive the Philistines out of their settlements (Jud. i. 18-19).

We reach more certain historical ground in the account of Shamgar's stand against the Philistines (Jud. iii. 31), but evidently the latter retained the supremacy, for we find them subsequently in possession of a sacred palladium of the Hebrews—the chest which was the symbol of Yahweh (I. Sam. iii. 10 sqq.). The story of Samson is of value as showing what were the relations between the Hebrews and Philistines. A victory is signalized for the Hebrews at Mizpah (I. Sam. vii. 10), but if the account is historical, the result was not decisive, for we find that Saul was constantly engaged in warding off their new encroachments, and at Gilboa he and his sons fell in a disastrous battle against them. David, however, though in the early part of his reign obliged to pay tribute to the Philistines, succeeded in routing them in several expeditions. Under Solomon they gave no further trouble, though it is doubtful whether they were ever actually tributary to the Hebrew kingdom. The internal troubles of Judea emboldened the Philistines once more to open resistance. Under Joram they invaded Judea and did considerable damage. Uzziah, however, recovered the lost ground; he overthrew them and dismantled some of their most powerful fortresses—Gath, Jabne, and Ashdod—and erected forts in different parts of their country. Under Ahaz, they rose again, and attacked the border cities of the 'plain' on the south of Judah; and a few years later renewed their attacks, in league with the Syrians and the Assyrians. Hezekiah, in the first years of his reign, subjugated their whole country again, by the aid of the Egyptians, whom we find in possession of five cities. The Assyrians were frequently engaged in conflicts with the Philistines, who at times joined the other Palestinian principalities in opposing the advance of Assyrian arms. In the struggles for supremacy which raged between the Neo-Babylonian monarchy and the Egyptians, Philistia was the constant battle-ground of both—her fortresses being taken and retaken by each of them in turn; so that the country soon sank into ruin and insignificance. In the time of the Maccabees the Philistines were subjects of the Seleucid rulers and had to suffer occasionally from the Jews, although intermarriages between the two nations were of no rare occurrence. Alexander Balas transferred part of the country to Judea; another part was taken by Alexander Jannæus; Pompey incorporated some of the cities with Roman Syria; Augustus transferred another portion to Herod; and, finally, Salome received a small fragment of it as a principality, consisting of Jamnia, Ashdod, and Ashkelon. But by this time the name of the country had long been lost in that of Palestine, which designated all the territory between Lebanon and Egypt.

Of the state of culture, institutions, etc., of the Philistines we know very little. They appear as a civilized, agricultural, commercial, and warlike nation. They traded largely, and their wares seem to have been much sought after. Their worship was much akin to that of the Phœnicians and Canaanites. Dagon, Ashtaroth, Beelzebub, and Derceto were the chief deities.

Müller, *Asien und Europa* (Leipzig, 1893); id., *Die Philister* (Berlin, 1899); G. A. Smith, *Historical Geography of the Holy Land* (London, 1897); McCurdy, *History, Prophecy, and the Monuments*, vol. i. (New York, 1894).

PHILISTINISM. A term made popular in England and America by Matthew Arnold. The allusion is to the ancient Philistines, the enemies of the children of light; hence Philistinism, in its modern application, means stolid opposition to the higher intelligence of the age, inaccessibility to ideas; plain, humdrum, respectable conventionalism. The German students first applied the term *Philister* to a townsman or to one who had not been trained in a university; it soon found a foothold in German literature, and reached England through Carlyle. The term has now grown hackneyed and its indiscriminate use has almost emptied it of meaning. Perhaps Leslie Stephen's definition of Philistinism, as "a term of contempt applied by prigs to the rest of

[illegible] is to be one that is sufficiently [illegible]-sive. Consult Arnold, "Heine," in *Essays in Criticism*, first series (Oxford, 1865).

PHILIS'TUS (Lat., from Gk. Φίλιστος, c.435-c.356 B.C.). A Greek historian of Syracuse. He assisted the elder Dionysius in securing and maintaining supreme power in Syracuse (c.405 B.C.), but in 386 was banished for marrying a niece of the tyrant without the latter's consent. Recalled soon after the accession of Dionysius the younger, he brought about the banishment of Dion and Plato, and according to the latter, employed his talents in defense of the despotic policy of Dionysius. In B.C. 356, however, he was defeated in a naval battle by Dion and the revolted Syracusans, and either committed suicide or was killed by the populace. He left *Sicelica* (Σικελικά), a history of Sicily from the earliest times to B.C. 362, in thirteen books, begun in exile. According to the testimony of the ancients, by whom he is frequently mentioned, he sought in this work to palliate the despotic deeds of Dionysius, in order to secure his own return from exile. In style he was a close, though unsuccessful, imitator of Thucydides. The few extant fragments of Philistus are edited in C. Müller's *Fragmenta Historicorum Graecorum* (Paris, 1841).

PHILLE'O. PRUDENCE (CRANDALL). See CRANDALL (PHILLEO), PRUDENCE.

PHIL'LIMORE, Sir ROBERT JOSEPH (1810-85). A distinguished English jurist, born in London. He was educated at Westminster and Christ Church, Oxford, where he graduated in 1831, and then became a clerk of the Board of Control. Soon afterwards he was called to the bar, where he acquired a large practice, and was made a Queen's counsel. In 1844 he was made Chancellor of the Duchy of Chichester, and later was a member of Parliament. He was made judge of the Cinque Ports in 1855, advocate-general in admiralty, 1862, when he was knighted, and in 1867 judge of the High Court of Admiralty and of the Arches Court of Canterbury. He was Judge Advocate-General, 1871-73, and made Master of the Faculties in the latter year. In 1875 he resigned his other offices, and was appointed judge of the Admiralty and Probate Division of the High Court of Justice, retiring in 1880. The most valuable of his numerous legal works is his *Commentaries upon International Law*, 4 vols. (3d ed., London, 1879-80). Among his other writings are *Memoirs and Correspondence of George, Lord Lyttelton, 1734-53* (ib., 1845); *The Ecclesiastical Law of the Church of England*, largely taken from the work of Burn upon that subject (2d ed., ib., 1895).

PHILLIMORE, Sir WALTER GEORGE FRANK (1845—). An English jurist, born in London. He was educated at Oxford, where he had a particularly distinguished career, became a barrister of the Middle Temple in 1868, and received the Patent of Precedence there in 1883. He stood high in the Admiralty Court, and in ecclesiastical circles as vice president of the English Church Union, and chancellor of the Diocese of Lincoln. He wrote a *Book of Church Law*, and edited Robert Phillimore's *Ecclesiastical Law of the Church of England*, and a third edition of vol. iv. of that author's *International Law*.

PHIL'LIP, JOHN (1817-67). A Scotch genre and portrait painter. He was born at Aberdeen, April 19, 1817. His boyhood was spent in poverty, but his remarkable talent attracted the attention of Lord Panmure, who enabled him to study at the Royal Academy. He at first painted Scotch genre subjects in the manner of David Wilkie, but a voyage to Spain in the summer of 1851-52, made for the benefit of his delicate health, completely changed his style. Influenced by Valazquez and by the bright colors of nature about him, he adopted the rich coloring by which his best works are distinguished. His work having attracted the attention of Sir Edmund Landseer, who introduced him to the Queen, he received a number of royal commissions, among which was a large ceremonial picture, "The Marriage of the Princess Royal with the Crown Prince of Germany" (1860). He visited Spain in 1856-57 and again in 1860, his last visit being a time of great artistic activity. After a journey to Rome and Florence in 1866, for the purpose of studying Titian, he was stricken with paralysis and died at Kensington (London), February 27, 1867.

Among the best paintings of his early period are: "Wallace and His Schoolfellows at Dundee" (1846); "Presbyterian Catechising" (1847); "Baptism in Scotland" (1850); "Scotch Washing" (1851). After his visit to Spain he executed "The Spanish Gypsy Mother" (1853), the "Letter-Writer of Seville," and the "Dying Contrabandista" (1858), all in the Royal Collection. Other important works are: "A Huff" (1859); the "Prison Window" (1857); "La Bomba" (1862-63); and his masterpiece, "La Gloria" (1864), in the National Gallery of Scotland. In the Metropolitan Museum, New York, is his "Gossips at the Well." He also produced a number of forcible portraits, including those of Sir J. E. Millais (1843), the Prince Consort (1858), and the Princess Beatrice (1860).

PHIL'LIPS. The name of a family identified with the founding of Phillips Academy (q.v.). SAMUEL, JR. (1751-1802), politician and philanthropist, was born at Andover, Mass. He graduated at Harvard in 1771 and was elected in 1775 to the Provincial Congress, of which he continued to be a member until 1780, when he was elected a member of the Massachusetts State Senate, of which for seventeen years (1785-1802) he was presiding officer. From 1781 until 1798 he was also judge of the Court of Common Pleas for Essex County, and in 1801 he was elected Lieutenant-Governor by the Federalists. He is best known, however, as the founder of Phillips Academy at Andover in 1778. In this project he interested his father, SAMUEL (1715-90), who graduated at Harvard in 1734, and afterwards represented Andover in the General Court; his uncles, JOHN (1719-95), who graduated at Harvard in 1735, settled at Exeter and was for many years a member of the Council of New Hampshire, and WILLIAM (1722-1804), who held important political offices in Massachusetts; and the latter's son, WILLIAM, JR. (1750-1827), who was in twelve successive elections chosen Lieutenant-Governor of Massachusetts. Their liberality enabled the academy to take a high position from the day of its opening. A few years later John Phillips, who was childless, founded at Exeter a similar academy, to which at his death he bequeathed two-thirds of his estate, the remaining third going to Phillips Andover. During his lifetime he also endowed a professorship at Dartmouth College, and made liberal gifts to Princeton.

PHILLIPS, ADELAIDE (1833-82). An American opera singer. She was born at Stratford-on-Avon, England, but when she was seven years old her family emigrated to America and settled in Boston. She first appeared at the Boston Museum, in 1843, as "Little Pickle," and played *soubrette* parts in that theatre and at the Walnut Street Theatre, in Philadelphia, until 1852, when, having revealed the possession of a contralto voice of remarkable sweetness and compass, she was sent to Italy for study, an advantage obtained largely through the efforts of Jenny Lind, who organized a subscription for the purpose. She remained abroad two years, and made a successful *début* in Brescia, in 1853, in *Semiramide*. The following year she returned to the United States, and appeared in concert in the Music Hall, Boston, making her American *début* in opera at the Academy of Music, New York, March 17, 1856, in the part of "Azucena" in Verdi's *Il Trovatore*. In 1861 she sang in the Italian Opera House in Paris. She was the leading contralto singer of America for many years. She died at Karlsbad.

PHILLIPS, EDWARD (1630-c.1696). An English compiler, the biographer of his uncle, John Milton. The poet's elder and only sister, Ann, on her second marriage left her two sons by her first to the care of her brother, who took them into his own house in Aldersgate. Edward was at that time ten years old, John a year younger, and besides his nephews, Milton took in other pupils. Edward ceased studying with him in 1646, and two years afterwards went to Oxford, where he departed from his Puritan training and joined himself to the Cavalier Party. Edward voiced his royalist sentiments in *The Mysteries of Love and Eloquence*, etc. (1658), containing verses some of which are not original, and to record the Restoration he wrote a *Continuation* (1665) to Barker's *Chronicle of the Kings of England*, which had stopped at 1641. He edited the poems of Drummond of Hawthornden (1656), compiled a dictionary (1658), and was tutor in more than one noble household, but was often obliged to support himself and his family by compilations and translations. John Philips never became reconciled to his uncle, but Edward did. He was the first to praise *Paradise Lost* in the press, spoke in the highest terms of its author in his *Theatrum Poetarum* (1675), and wrote the scant but appreciative *Life of Milton* prefixed to the *Letters of State* (1694).

PHILLIPS, HENRY (1838-95). An American archæologist, born in Philadelphia. He was admitted to the bar in that city in 1859, but, because of ill health, devoted himself to the study of numismatics, philology, and archæology. His publications include *History of American Colonial Paper Currency* (1865); *History of American Continental Paper Money* (1866); *Pleasures of Numismatic Science* (1867); a volume of Spanish and German poetry (1878); Chamisso's *Faust* (1881); and four volumes from the Hungarian, German, and Spanish (1884-87).

PHILLIPS, JOHN (1800-74). An English geologist, born in Wiltshire. After receiving an elementary education he joined his uncle, William Smith, in geological investigations in various parts of England. In 1825 he was made curator of the Yorkshire Philosophical Society, and in 1834 was appointed professor of geology at King's College, London. Resigning this office in 1840, he served successively as geologist on the survey of Great Britain, professor of geology at Trinity College, Dublin, and at Oxford, and Keeper of the Ashmolean Museum. He was president of the Geological Society in 1859-60. He contributed numerous papers to scientific journals, and also wrote the following separate works: *Illustrative of the Geology of Yorkshire* (1822-36); *Guide to Geology* (1834); *Treatise on Geology* (1837); *Geological Map of the British Isles* (1842); *Memoirs of William Smith* (1844); *Vesuvius* (1869); and *The Geology of Oxford and the Valley of the Thames* (1871).

PHILLIPS, JOHN ARTHUR (1822-87). An English geologist, born at Polgooth, near St. Austell, Cornwall, and educated at the Paris School of Mines. He was appointed chemist to the Admiralty commission engaged in finding the most suitable coal for burning at sea, and afterwards made valuable researches in mineralogy. He inspected gold mines in California and elsewhere, and between 1875 and 1878 he wrote a series of important monographs on the rocks of his native country. He published *The Mining and Metallurgy of Gold and Silver* (1867), and *The Elements of Metallurgy* (1874), but his chief work was *A Treatise on Ore Deposits* (1884).

PHILLIPS, PHILIP (1834-95). A Methodist evangelist and singer. He was born in Chautauqua County, N. Y. After the age of nineteen he devoted all his time to the study and use of music. During the Civil War he sang much for the benefit of the Christian Commission; he became musical editor for the Methodist Book Concern in 1866; and made a musical tour around the world in 1872, holding evenings of song in all lands. On his return he gave 200 nights for the Sunday School Union in England; subsequently he traveled with D. L. Moody. He produced a number of hymn books, such as *Early Blossoms* (1860); *The Singing Pilgrim* (1866); *American Sacred Songster*, prepared for the British Sunday School Union (1868); *Hallowed Songs* (1871); *Our New Hymnal* (1894); and, with his son, *Bright Gems* (1895). Several of these had a very large sale.

PHILLIPS, STEPHEN (1868—). An English poet, born at Summertown, near Oxford, July 28, 1868, son of the Rev. Stephen Phillips, afterwards precentor of Peterborough Cathedral. Having attended the grammar school at Stratford-on-Avon and at Peterborough, he studied for the civil service and entered Queen's College, Cambridge, in 1886, but at the end of the first term he joined F. R. Benson's company of Shakespearean players, with whom he stayed six years. He traveled through the country and played at the Globe Theatre in London. Among his parts were Iago, the ghost in *Hamlet*, Prospero, Brutus, and Sir Andrew Aguecheek. Leaving the stage, he became a lecturer on English history in Wolfram and Needham's classes for army candidates, but soon he adopted literature as a profession. In June, 1890, with three other authors he published in London a booklet of verse entitled *Primavera*. In 1894 followed *Eremus*, which won the praise of Symonds, Jowett, and Stopford Brooke. *Christ in Hades and Other Poems* (1896; fourth edition with additions, 1897), and *Poems* (1897), containing "Marpessa," secured for the author a high rank among

recent poets. *The Poems* won from the London *Academy* the award of one hundred guineas for the best verse of the year. Commissioned by George Alexander to write a verse tragedy for Saint James's Theatre, Phillips composed *Paolo and Francesca* (1899), a poetic tragedy in four acts. The blank verse of this lyric tragedy recalls the Elizabethans, but its simple structure is more nearly akin to the French classic drama. For Beerbohm Tree Phillips wrote his second play, *Herod* (1900), a tragedy in three acts on an Elizabethan theme. *Ulysses*, a dramatic poem, appeared in 1902, and in the same year a play called *David and Bathsheba*.

PHILLIPS, THOMAS (1770-1845). An English portrait painter, born in Dudley, Warwickshire. He was a pupil of Francis Eginton, a glass painter of Birmingham, and afterwards worked under Benjamin West on the windows of Saint George's Chapel, Windsor. He began to exhibit at the Royal Academy in 1791 and was elected to that institution in 1808. There he succeeded Fuseli as professor of painting and his *Lectures on the History and Principles of Painting* were published in 1833. His portraits include those of the Prince of Wales, William Blake (in the National Portrait Gallery), Napoleon (at Petworth), Lord Byron (two pictures), Crabbe, Lord Brougham, David Wilkie (in the National Gallery), Walter Scott, Hallam, Faraday, and Davy.

PHILLIPS, WENDELL (1811-84). An eminent American orator and reformer, born in Boston. He was educated at Harvard, graduating in 1831—the year of the first appearance of the *Liberator*. After a three-years' course at the Cambridge Law School, he was admitted to the Suffolk County bar; but he was little interested in professional eminence. On October 21, 1835, from his office window he indignantly saw Garrison dragged at a rope's end by a respectable mob; in 1836 he joined the Abolitionists, and thereafter was occasionally heard at meetings of the American Anti-Slavery Society. He came at once into prominence by his Faneuil Hall speech of December 8, 1837. At the instance of Dr. W. E. Channing, a public assembly had convened to protest in a suitable manner against the murder of the Rev. E. P. Lovejoy (q.v.) at Alton, Ill. This purpose seemed likely to be defeated by J. T. Austin, Attorney-General of Massachusetts, who commended the Alton rioters, and affirmed that Lovejoy "died as the fool dieth." To this Phillips made a brilliant and crushing reply, whose eloquence he never surpassed, and which has been ranked by Curtis with Henry's oration at Williamsburg, and Lincoln's Gettysburg address. From that time he was an Anti-Slavery leader, to eminently the orator of the movement. In 1839 he withdrew from the practice of law through scruples against compliance with the attorney's oath to the Constitution, and later he refused to stand for a Congress which he could not enter without swearing allegiance to that same Constitution. He called for the immediate and complete abolition of slavery, declared the Church *particeps criminis* for its attempt to justify slavery by the Scriptures, opposed colonization for the negro, discontinued voting, and advocated disunion as the best means for accomplishing emancipation. He was not to accept Garrison, a non-resistant. In the Abolitionist divisions of 1839-40, he with Garrison opposed the organization of the Abolitionists in a political party, and the attempt to bar any from the anti-slavery platform on the ground of religious beliefs. In 1840 he was the representative of the Massachusetts Abolitionists at the London World's Anti-Slavery Convention. Differences arose between himself and Garrison in 1864, in regard to Lincoln's reëlection, which he did not favor; and in 1865 these differences were renewed when he advocated and Garrison opposed the continuance of the Anti-Slavery Society. His contention was that the work of the society was not finished until the negro obtained the suffrage. As a result he was elected in Garrison's stead (1865) to the presidency of the society, which was dissolved in April, 1870, upon the passing of the Fifteenth Amendment. Phillips was prominently active in the various controversies of the Reconstruction. Yet his task did not end there. "Let it not be said," he once wrote, "that the old Abolitionist stopped with the negro, and was never able to see that the same principles claimed his utmost effort to protect all labor, white and black, and to further the discussion of every claim of humanity." Accordingly, he spoke in behalf of Ireland, Crete, the Indian, prison reform, the abolition of capital punishment, prohibitory legislation regulating the sale of liquor, the 'greenback theory,' and in connection with the labor question urged that vast combinations of capital with unlimited monopolies and powers tend to make the rich richer and the poor poorer. In 1870 he received about 20,000 ballots as labor reform and temperance candidate for the Governorship of Massachusetts.

Phillips must be compared among American orators to Everett, Clay, and Webster; and his achievement is, perhaps, to be reckoned greater than that of any of these, when it is considered that whereas they represented a strong political organization or powerful conservative opinion, he attacked existing prejudices and institutions, for years spoke to hostile audiences, was denounced by the two great parties, and belonged to none. His manner was that of "simple colloquy," so that Greeley said Phillips made one think it easy to be an orator. His voice was in the baritone register, used largely in what elocutionists call the upper chest notes, and remarkable not so much for its compass, volume, or intensity as for its *timbre*. In gesture or general action he was sparing. He seldom employed the dramatic mode of expression. But in invective or epigram he was unsurpassed, he possessed wit, which most other notable American orators have lacked, and he told an anecdote with much skill. Phillips was not a scholar in the restricted sense, for this the demands made upon his time as a public speaker did not permit. But his reading was considerable, and he could always find illustrative material in the one subject he was accustomed to say he knew thoroughly—the great English Revolution. In addition to his anti-slavery and other reform speeches, he appeared in various lyceum addresses, the most noteworthy of which are *The Lost Arts*, *Toussaint l'Ouverture*, and *Daniel O'Connell*, and in 1881 he made a distinguished oration on *The Scholar in a Republic* at the centennial anniversary of the Phi Beta Kappa of Harvard. During anti-slavery days he always offered to speak without remuneration and pay

his expenses if he might substitute an anti-slavery for a literary subject. He wrote for the *Liberator* and the *Anti-Slavery Standard*, and published a number of pamphlets, including *The Constitution a Proslavery Compact* (1844); *Can Abolitionists Vote or Take Office Under the United States Constitution?* (1845); *Review of Spooner's Unconstitutionality of Slavery* (1847); *Review of Webster's Seventh-of-March Speech* (1850); *Review of Kossuth's Course* (1851); *Defense of the Anti-Slavery Movement* (1853). Collections of *Speeches, Lectures* and *Letters* have appeared at Boston, the first series, edited by James Redpath, in 1864, the second by T. C. Pease in 1892. These are edited from the best stenographic reports. There are two inadequate biographies, one by Austin (Boston, 1888), the other by Martyn (New York, 1890; American Reformers Series). Consult also works dealing with the anti-slavery struggle.

PHILLIPS ACADEMY. An important boys' school at Andover, Mass., commonly known as Phillips Andover. It was founded and opened in 1778 through the gifts of members of the Phillips family. The school was incorporated in 1780, and in 1807 the trustees were empowered to receive and hold funds for a separate theological institution, and the Andover Theological Seminary was accordingly established in the following year. In 1830 the Teachers' Seminary was established in anticipation of the normal schools, but in 1842 was merged in the parent academy, and is its present scientific department. In 1901 an archæological department, with valuable collections and an endowment for instruction, research, and publication, was established by two anonymous donors. The Academy, with its sister institution at Exeter, has always been regarded as a typically democratic American school. During the early years of its history it had as students many of the famous men of the country. The equipment has in recent years been largely increased by new buildings, among them several dormitories and a gymnasium. The standards of Yale and Harvard, to which most of the graduates go, form the basis on which the work of the school is arranged. The academy had in 1902 an attendance of 400 and 24 instructors. The endowment was $400,000, the gross income $70,000, and the college property was estimated at $500,000, exclusive of invested funds. The library contained 60,000 volumes.

PHILLIPS ACADEMY. One of the oldest and most renowned of American schools, at Exeter, New Hampshire, commonly known as Phillips Exeter. It was founded in 1781 and opened in 1783. The school was the first educational institution incorporated by the Legislature of New Hampshire, and has its name from John Phillips, its founder, who was a generous benefactor of Dartmouth College and of Phillips Academy, Andover, Mass. It early gained a national reputation, and drew students from all sections of the country. The alumni in 1903 numbered about 7000, among its earlier students being Daniel Webster, George Bancroft, Edward Everett, John A. Dix, and Jared Sparks. In 1902-03 over 300 students were enrolled and the faculty numbered 16. The school buildings, many of which have been built since 1886, include well-equipped laboratories, fine dormitories, an administration building, gymnasium, and a building designed as a common dining-room and for the entertainment of visiting alumni. The buildings with their equipment are valued at about $300,000. The endowment in 1902 was about $400,000, and the annual income $100,000. Characteristic of the school have been its democratic spirit and its successful application of a system of self-government.

PHIL'LIPSBURG. A town in Warren County, N. J., on the Delaware River, opposite Easton, Pa., and on the Pennsylvania, the Lehigh Valley, the Lackawanna, and the Central of New Jersey railroads (Map: New Jersey, B 2). It possesses valuable advantages for an industrial centre, the river affording good water-power and the railroads making accessible a supply of coal and iron ore. Its manufacturing interests are extensive, and include shops of three of the railroads that enter the town, also iron furnaces, sheet iron mills, foundries and machine shops, stove works, boiler works, horseshoe mills, drill works, and large silk mills. Settled in 1749, Phillipsburg was incorporated in 1861. It is governed under a revised charter of 1875, by a mayor, annually elected, and a council which controls appointments of most of the subordinate officers. Population, in 1890, 8644; in 1900, 10,052.

PHILL'POTTS, EDEN (1862—). An English novelist, son of Captain Henry Phillpotts. He was born at Mount Aboo, in India, November 4, 1862, and was reared at Plymouth, England. At the age of eighteen he became clerk in the Sun fire insurance office—a position which he held for ten years. A number of earlier novels were followed by two great successes, *Lying Prophets* (1897) and *Children of the Mist* (1898). In these novels Phillpotts depicted Devonshire life with remarkable power and beauty. In their coloring they recall Blackmore, and in their tragedy they are akin to Hardy. There have since followed *Loup Garou* (1899); *The Human Boy* (1899), which is a volume of stories illustrating schoolboy humor; *Sons of the Morning* (1900); *The Striking Hours* (1901), a collection of short Devonshire stories; *The Good Red Earth* (1901); and *The River* (1902).

PHI'LOBIB'LON. A prose treatise by Richard Aungerville, known as Richard de Bury, Bishop of Durham (1345). The author, an enthusiastic collector of books, and founder of a library at Oxford in connection with Durham College, writes in praise of learning, of the value and proper care of books, with advice to students. It was printed first at Cologne in 1473, at Paris in 1500, and at Oxford in 1599. The latest English translation is that of E. C. Thomas (London, 1888).

PHI'LO BYB'LIUS. See SANCHUNIATHON.

PHILOCH'ORUS (Lat., from Gk. Φιλόχορος). A Greek historian who is said to have lived at Athens between B.C. 306 and 260. According to Suidas, he was one of the bitterest opponents of Demetrius Poliorcetes and of his son, Antigonus Gonatas, and was put to death by the latter after the conquest of Athens (about B.C. 260). He is known chiefly by his *Atthis*, a history of Athens from the earliest times to B.C. 262, in seventeen books. By later writers it is frequently referred to as one of the most thorough and reliable of the special histories of Attica. Important fragments are preserved in Müller's *Fragmenta*

Historicorum Græcorum (Paris, 1841). Consult: Strenge, *Quæstiones Philochoreæ* (Göttingen, 1868), and Siebelis's edition (Leipzig, 1811).

PHILOCTE'TES (Lat., from Gk. Φιλοκτήτης, *Philoktētēs*). A Greek chieftain who inherited the bow and arrows of Heracles. He started with seven ships for the Trojan War, but was bitten on the way by a serpent at Lemnos. On account of the stench of the wound, the other Greeks left him behind and went on to Troy. As an oracle, however, declared that Troy could only be taken by the arrows of Heracles, Odysseus and Diomedes went to Lemnos to fetch Philoctetes. He accompanied them to Troy, slew Paris, and returned safely home. The drama *Philoctetes* by Sophocles is still extant, the legend having been also dramatized by Æschylus and Euripides.

PHILODE'MUS (Lat., from Gk. Φιλόδημος). An Epicurean philosopher of the first century B.C. He was born at Gadara in Syria, and studied under Zeno. Besides thirty-four epigrams, mostly erotic, in the Greek anthology, Philodemus wrote works on philosophy, of which copies much mutilated were discovered at Herculaneum. They are: *De Rhetorica*, edited by Gros (1840) and by Sudhaus (1892-95); *De Musica*, edited by Kempke (1884); *De Vitiis*, by Göttling (1830) and Ussing (1868); *De Ira* and *De Pietate*, by Gomperz (1864-66); and *De Morte*, by Mekler (1886). Martha makes him the editor of Lucretius and many attempts have been made to prove that Cicero got his knowledge of Epicureanism from Philodemus and so from Zeno.

PHI'LO JUDÆ'US (Lat., from Gk. Φίλων Ἰουδαῖος, *Philōn Ioudaios*, Philo the Jew). A Jewish-Hellenistic philosopher, born at Alexandria about B.C. 25. He belonged to one of the most wealthy and aristocratic families—his brother Alexander was the Alabarch or president of the Jewish colony at Alexandria—and he received the most careful Jewish education, consisting largely of a study of the Old Testament in the Septuagint version. He also became acquainted with the writings of the Greek philosophers. He went to Rome, A.D. 39 or 40, as the advocate of his Alexandrian brethren, who had refused to worship Caligula in obedience to the Imperial edict. He has left an account of this embassy, the result of which was not satisfactory. Of his life we know little except what is recorded above.

While strict in all that pertained to ceremonial and ritual, in doctrinal matters Philo was a bold allegorizer. A literal interpretation of the Scriptures he regarded as superstitious and mean. Especially did he explain away all theophanies recorded in the Old Testament, as told in accommodation to the sensuous character of human minds, which needed anthropomorphic representations of supersensible truth.

His writings develop his ideas and his system in the two directions indicated. In that division of his writings principally which treats of the creation (*Kosmopoïa*), he allows allegory to take the reins out of his hands; in that on the laws (*Nomoi*), on the other hand, he remains remarkably sober and clear, extolling the Mosaic legislation throughout, at the expense of every other known to him. In a very few instances only he is induced to find fault, or to alter slightly, by way of allegory, the existing ordinances.

His idea of God is a preëminently theosophic not a philosophic one. God alone is the real good, the perfect, only to be imagined as the primeval light, which cannot be seen by itself, but may be known from its rays, that fill the whole world. He has no attributes, and therefore no name, and reveals himself only in designations expressive of this 'inexpressibility.' He is better than virtue and knowledge, better than the beautiful and the good (*Kalokagathia*), simpler than the one, more blissful than bliss. He is the existing unity or existence itself, self-sufficient, free from pain and fear and participation in evils, and full of happiness. Dynamically God is omnipresent, but not really. Indeed, so far is God really from filling the world with his presence that the world, on the contrary, finds its place in God. And yet the God who comprehends within himself the material universe is so exalted above the world and so remote from it that a point of contact cannot be found between them; hence the need of an intermediate class of beings to stand between them. These were found in the spiritual world of ideas, which are not only 'ideals,' or types, in the Platonic sense, but real, active powers, surrounding God like a number of attendant beings. They are his messengers, who work his will, and by the Greeks are called good demons; by Moses, angels. There are very many different degrees of perfection among them. Some are immediate 'serving angels;' others are the souls of the pious, of the prophets, and the people of Israel, who rise higher up to the deity; others again are the heads and chief representatives of the different nations, such as Israel does not need. The *Logos* comprises all these intermediate spiritual powers in his own essence. (See article Logos for Philo's views on this part of his system.) Man is a microcosm, a little world in himself, a creation of the Logos, through whom he participates in the deity. The ethical principles of Stoicism Philo identified with the Mosaic ethics, in which the ideal is most exalted moral perfectibility or sanctity, and man's duties consist in veneration of God, and love and righteousness toward fellowmen. Philo holds firmly the belief in immortality. Man is immortal by his heavenly nature; but as there are degrees in his divine nature, so there are degrees in his immortality, which only then deserves this name when it has been acquired by an eminence of virtue. There is a vast difference between the mere living after death, which is common to all mankind, and the future existence of the perfect ones. Virtue and sin both have all their rewards within themselves; but the soul, which is 'pre-existing,' having finished its course in the sublunar world, carries this consciousness with it in a more intense and exalted manner. Paradise is oneness with God; there is no hell with bodily punishments for souls without a body, and no devil in the Philonic system. (For the relation between Philo, as the representative of the Judeo-Alexandrian philosophy, and other contemporary philosophic tendencies, see NEO-PLATONISM). Of the many works left under his name, several have been declared spurious, but in some cases without much show of reason. His writings have been published by Richter (Leipzig, 1828-30) and by Tauchnitz

(ib., 1851-54). See Gfrörer, *Philon und die alexandrinische Theosophie* (Stuttgart, 1831); Dähne, *Geschichtliche Darstellung der jüdisch-alexandrinischen Religionsphilosophie* (Halle, 1834); Wolff, *Die philonische Philosophie* (Leipzig, 1849); Delannay, *Philo d'Alexandrie* (Paris, 1867); Drummond, *Principles of the Jewish-Alexandrian Philosophy* (London, 1877); id., *Philo Judæus* (ib., 1888); Freudenthal, *Die Erkenntnislehre Philos von Alexandria* (Berlin, 1892).

PHIL'OLA'US (Lat., from Gk. Φιλόλαος) (c.450 B.C.). A Pythagorean philosopher, born at Tarentum or Croton. Little is known of his life. Some fragmentary writings are attributed to him, in which he sets forth the teachings of Pythagoras. The authenticity of these writings has been the subject of serious study and of dispute among critics. To him is ascribed a knowledge of harmonic ratio, and of the fact that the number of vertices of a cube is an harmonic mean between the number of faces and the number of edges. He seems also to have known with reasonable exactness the periods of revolution of the planets. Consult: Boeckh, *Philolaus des Pythagoräers Lehren, nebst Bruchstucken seines Werkes* (Berlin, 1819); Schaarschmidt, *Die angebliche Schriftstellerei des Philolaus* (Bonn, 1864).

PHILOLOGICAL ASSOCIATION, American. A learned society, organized at Poughkeepsie, N. Y., in July 1869, from the Classical Section of the Oriental Society (q.v.), with Prof. William D. Whitney, of Yale, as the first president. Its object is the advancement and diffusion of philological knowledge. It has a membership of about 600, and its annual meetings are held in such cities as the society may, from year to year, select. The publications of the association are annual volumes of *Transactions*, in which are printed in full such papers as the executive committee may select, and *Proceedings*, giving an account of the annual meeting and brief abstracts of all papers presented to the society.

PHILOLOGICAL SOCIETY, British. A learned society founded in London in 1842, to investigate and promote the study and knowledge of the structure, the affinities, and the history of languages. It added to these objects the publication of the 'New English Dictionary,' work upon which was begun in 1857, under the editorial charge of Dr. James A. H. Murray, assisted by many scholars and men of science in Great Britain and the United States. The first part was published in 1884, and the bound volumes issued to 1903 bring the Dictionary down to the letter M, though some parts in O and Q have also been sent out in pamphlet form. The society has its headquarters at University College, London, and holds its annual meeting in May and monthly meetings from November to June, at which papers are read, the more important ones being afterwards published in volumes of *Transactions*, distributed to members without charge, while summaries or synopses of the other papers are printed in the monthly *Abstract*, also published by the society.

PHILOL'OGY (Lat. *philologia*, from Gk. φιλολογία, love of literature and learning, love of language and history, from φίλος, *philos*, dear + λόγος, *logos*, word). In modern English usage, the science of comparative linguistics. As speech may be studied either in its expression or in its origin, philology may occupy itself with linguistic expression, with literature, or with the genesis and laws of language. French and German scholars usually employ the word in the former sense, and many English scholars prefer to understand by philology the study of literary expression, even including all that is revealed through literature. Nevertheless, although this is perhaps the more legitimate use of the word, yet the tendency of the day, even among French scholars, and still more among English-speaking people, is to confine philology to the study of language, and to divide this study into (a) linguistics proper, including phonetics, and (b) comparative philology, the study of language by a comparison of different languages in the same family. Languages may be divided roughly, and merely for convenience without scientific accuracy, into several types. Of these the most important are the isolating or monosyllabic, the agglutinative, with its subdivision the incorporating or synthetic, the inflectional, and the analytic. The isolating group, formerly supposed to be represented by Chinese, is characterized by invariable monosyllabic roots. The opinion which once considered this group to be the most primitive is now rejected by many who hold that the type represents, on the contrary, the culmination of a long linguistic evolution. The agglutinative type, which includes the majority of languages, such as the Dravidian, Malayo-Polynesian, Uro-Altaic, and African, is marked by the addition of prefixes, suffixes, and infixes to the so-called root (q. v.) or base. These additions have, at least at first, distinct meanings of their own, but in course of time the meanings become obscured, the particles themselves become fused in signification with the base, and lose their individuality. The result is the type of language called inflectional. (See Inflection.) In the incorporating or polysynthetic languages, represented by the American Indian groups, the verb absorbs the name, pronouns, adjectives, and adverbs, thus marking a higher degree of agglutination than the agglutinative languages themselves. The analytic languages are a development of the inflectional. In time the inflections tend to become weakened in force, and to require the help of pronouns, prepositions, and auxiliary verbs. When the inflections have in the main disappeared, and their places have been taken by individual words, the language is termed analytic. To this group belong such languages as English, French, Italian, Persian, and Hindustani, as distinguished from the inflectional groups represented by the Semitic and Indo-European families, which include Hebrew, Arabic, Sanskrit, Greek, Latin, and German. It is, however, customary to confine comparative philology to the study of the group of Indo-European languages, though there is no reason why the term should not be applied to any other group as well. The different aspects of philology thus outlined are treated under different heads, to which the reader is referred for special discussion. See the articles on Language, for the psychology of language; Albanian, Armenian, Indo-Iranian, etc., for special branches; and for classical philology, see the articles on Greek Language and Italic Languages.

History of Comparative Philology. Until the discovery of Sanskrit no comparative philology was possible. Sir William Jones in 1786 and Schlegel in 1808 connected Sanskrit with Greek and Latin; but Franz Bopp (q.v.) first correlated the facts observed by others and founded the science. Approaching the subject from the philosophical side, Bopp devoted himself to glottogonic problems, his chief aim being to discover phonetic laws and the genesis of forms. He was at first influenced by Friedrich Schlegel, and opposed the doctrine of mechanical affixes (called agglutination), holding rather to an inner inflection as the index of different relations, though he admitted into the root (in the aorist, etc.) the abstract verb *as*, 'be.' But this view (1816) was soon changed, and Bopp in 1819 himself opposed this philosophy of language and taught that verbal endings, *-ti* for example, are really pronominal in origin. In his *Conjugationssystem* and *Vergleichende Grammatik* (1833) he went still further, assuming a pronominal origin for case-endings as well as verbal endings (*-s* of the nominative being *sa*, 'he,' etc.). It is unnecessary to give in detail the mixture of fact and fancy which from a later point of view, alternately adorns and disfigures this first exhaustive attempt to create a science of grammar. His monumental work was followed by the equally important *Geschichte der deutschen Sprache* (1848) of Jakob Grimm (q.v.), who with Rask (q.v.) extended the comparison of forms and discovered phonetic laws of change (see below). After Grimm, the *Etymologische Forschungen* (1836) of Pott (q.v.) established a rationalized system of etymology for the whole group of Indo-European languages. Bopp, Grimm, and Pott may justly be called the creators of the comparative study of language. Agglutination, monosyllabic roots, *a*, *i*, *u*, as the three essential vowels, and a mother-language, these characterize the belief of the first period of the study represented by them. This period extends to the appearance of Schleicher's (q.v.) *Compendium* (1862), which systematized the views of his predecessors, while adding to them his own more stringent but false conception of language as a living organism, which in his opinion should be studied by the methods of natural science. An increasing respect for 'phonetic law' (q.v.) marks the close of this period, in which the names of Schleicher and Georg Curtius (q.v.), the latter being one of the first to insist on phonetic regularity, are most prominent. Different languages now began to be studied more carefully, each for itself, and the laws of each more strictly established. New problems arose, such as that of the parent language and primitive vocalism, but Schleicher stood on the platform of his predecessors as regards the old problems. The parent speech Schleicher represented as the root of a tree, with trunk, branches, and twigs representing descendant languages and dialects (the so-called *Stammbaum Theorie*). Like Curtius, he held that the simpler vocalism of Sanskrit was more antique than the variation shown in Europe, and believed that Sanskrit *a* was older than Greek *α*, *ε*, *ο*.

Ten years later, in 1872, Johannes Schmidt (q.v.) published his *Verwandtschaftsverhältnisse der indogermanischen Sprachen*, which put the interrelation of the different Indo-European languages in a new light. Instead of a family-tree with its organic growth and dialect-twigs, Schmidt set forth the *Wellentheorie*, according to which the different languages had rolled away like waves from a common centre. This view replaced Schleicher's and in a somewhat modified form has been adopted by Leskien, Schrader, and other scholars of the present day. According to it, certain words and forms are explained as being common to one section till that splits up and so leaves the contiguous peoples in possession of a common linguistic property, while those dwelling farther apart possess linguistic property which, although originally practically identical, has become so differentiated as frequently to be mutually unintelligible. The obvious objection is that some wave-segments may have lost material formerly possessed and others made for themselves what is also found in other segments. This change of view is paralleled by that in regard to vocalism. Instead of assuming that the primitive language had only *a*, *i*, *u*, and that Sanskrit *a* was an older phase as compared with Greek *α*, *ε*, *ο*, the scholars of the second period, which began about 1862, Brugmann, Osthoff, Collitz, and others, showed that the varied phase was older. During this period, as for a dozen years previously, much of the best effort of philologists was directed toward individual languages, the publication of texts, lexicons and grammars, which gave much new material in many directions, notably in the Indo-Iranian field. Benfey, Roth, Böhtlingk, Westphal, Curtius, and Max Müller thus furthered the cause of general comparative philology. Moreover, new languages were added to the group, such as Albanian, Armenian, and Phrygian. At this time also began to be discussed afresh the problem of new formations. The answer to this was given in Whitney's enunciation of the theory of analogy (q.v.). By imitation of the old, the new is produced. But especially were the scholars now calling themselves young grammarians insistent upon one principle which became a shibboleth. This was the invariability of phonetic law (q.v.). In the seventies and eighties the various philologists of note in Germany were more or less split up into cliques headed by Georg Curtius, Fick, Schmidt, Brugmann, and others, but this was due less to a radical difference than to personal feeling and may be passed over. In America, Whitney centred his attention upon the fundamental question of the origin and growth of language, and in so doing came into conflict with Max Müller. Müller claimed that language gives conceptions which could not exist without speech. Thought and word were, in his view, convertible terms. Whitney held, on the other hand, that words are only signs associated with conceptions, and that every language known to us is a body of conventional signs for ideas. Müller denied that any man can change a language; Whitney maintained that individuals initiate changes subsequently accepted by the community, which makes the changes parts of its language by the simple employment of them. To Müller, language-study was a physical science, even in his final revision of the views first expressed in 1862. In all this, Müller showed that he was of the school of Schleicher, whom, indeed, he cited as his chief authority in teaching that the study of language is a physical science. Language is, however, a human institution, not a physical science, and the failure to recognize this fact undermines the foundation of Müller's

view. Müller further held that no new roots have ever been made since the original root-making period, and he treated these primitive roots as if they were necessarily non-derivative forms. In point of fact, many of the 'roots' of the primitive tongue may be reductions from compound words comparable to 'preach' and 'cost' in English. (See ROOT.) Such primitive roots in Müller's opinion, however, are ultimate facts, the nuclei in a chaos of interjectional or imitative sounds. Whitney upheld the view that language was composed of a body of conventional signs originally of depictive character of any sort, onomatopoetic or not. In one respect only was there an advance in Müller's system on Schleicher. He accepted the 'physical science' view of language, but he rejected the notion of a primitive Indo-European language from which Sanskrit, Greek, Latin, Germanic, Slavonic, and Celtic were derived, though even here he spoke of the mother-language of the whole family. At the same time he argued that where in two dialectic forms of one word there are two different consonantal sounds they must go back to an indistinct pro-ethnic consonant capable of developing into either, which is, in the premises, an impossible assumption. It is remarkable that German scholarship added little to the discussion of these fundamental questions. An exception, however, must be made in favor of Paul, whose *Prinzipien* (1880) discussed at length and acutely the causes leading to phonetic and morphologic changes. On the other hand, all the great discoveries of comparative philology have been made by Continental scholars.

THE FIELD OF INVESTIGATION. Turning now from this historical outline of the growth of the science of philology to the subject-matter of the science, it will be necessary first to explain the field of investigation. Comparative philology as applied to the Indo-European or Indo-Germanic languages (q.v.) first demarcates those languages from others. This family constitutes a single group, separated both by vocabulary and by structure from other groups of languages. Whether the Indo-European group had at any time a common origin with other groups passes human knowledge. Many scholars (Ascoli, Abel, and others) have made abortive attempts to connect Indo-European forms with Semitic, Mongolian, and Egyptian forms, but nothing cogent has been produced to show that there is any radical affinity between them, though there has often been connection. The name Indo-European is only one of many, but at present the usual one, to designate the group called in German quite as often Indo-Germanic, and in English frequently Aryan. The last name is one often used by German scholars to designate the narrower group of Indo-Iranian. The members of the Indo-European group are the sub-groups known as Indic, Iranic, Anatolic, Hellenic, Celtic, Teutonic, Balto-Slavic. Some scholars add Albanian as a separate sub-group and some particularize Armenian as a subdivision on a par with Hellenic (see below). These sub-groups include a great number of languages and dialects, various in themselves and in some cases intricately combined. The chief elements making each group are:

INDIC. Sanskrit and the pre-Sanskrit Vedic language. The former name is often made to cover both divisions, but, like English in relation to Anglo-Saxon, though conveniently used, it is not accurate. There was no Sanskrit language till after the Vedic period. Whether Sanskrit is derived from the Vedic may be doubted. It is closely connected with that earlier language, but it is quite possible that the two are dialectic variations from the start. Evidence given by the Linguistic Survey of India seems to show that there were two main Aryan invasions of India, entering by two different routes and at different times; that those speaking the Vedic language were the first comers, afterwards pressed to the wall by the ancestors of those who in course of time spoke what we call Sanskrit. Opposed to Sanskrit is Prakrit (q.v.), a general term for various dialects recognized at an early date as being not Sanskrit and yet not foreign. The language of Hinayana Buddhism, Pali (q.v.), was one of these patois. It is closely related to the Vedic language, and may be as old. Corresponding to the patois Prakrit dialects of antiquity are the modern provincial dialects, Bengali, Panjabi, etc., reflecting, however, more or less the effect of Sanskrit. A European offshoot of this division is the Gypsy language of Europe, many of whose words (verbal roots) are still identical with those of Sanskrit. (See GYPSIES.) The oldest literary remains of this group are from B.C. 1000 to 1200, though some scholars assign a much greater antiquity to the Vedas, the earliest Indic literature.

IRANIC. This group, the name of which is derived from Iran (Eran), the great plateau including Persia, Afghanistan, and Baluchistan, can be traced from quarters contiguous with the Indic group, and is closely connected with the latter. In fact, Indic and Iranic (Aryan in the narrower sense) are both dialects of the same language rather than separate languages. Especially is this true of the Old Bactrian (Avestan or Zend) division of Iranic (see AVESTA), the sacred literature of which extends back to about the seventh century B.C. Opposed to this division is the Old Persian (q.v.), sometimes called the Western dialect in antithesis to Avestan as the Eastern. Old Persian is the language of the cuneiform inscriptions of the Persian kings, and this alone survived as a spoken language, being gradually modified into Pahlavi (q.v.) and New Persian. See PERSIAN LANGUAGE.

ANATOLIC. This group comprises Armenian (which was formerly regarded as Iranic and is now sometimes accorded a separate division), Phrygian (q.v.), and Scythian, and until lately was supposed to be represented by Lycian and Carian also. Later investigations, however, have shown that the two latter do not belong to the Indo-European group, and Scythian applies only to such remnants of Indo-European origin as are represented by some of the names of nomads in Southern Russia and on the border of Asia Minor. As such the division is maintained by Fick, but it rests on very doubtful evidence. The oldest literature is of the fourth century, unless the recently (1902) interpreted 'Arzawa' language assigned to Cappadocia be regarded as Indo-European (c.1400 B.C.).

HELLENIC. This comprises all the old Greek dialects, Ionic, Doric, etc.; Albanian, a mixture of Greek and foreign elements; also the modern dialects of Greece. (See GREEK LANGUAGE.) The literature goes back to about B.C. 1000.

ITALIC. This division includes Latin, Umbrian, Oscan, and other minor dialects; modern dialects,

in part primitive, in part due to foreign elements, Italian, Provençal, French, Spanish, Portuguese, Roman, etc., called in general Romance. The literature goes back to the third century B.C. inscriptions still older). See LATIN LANGUAGE; ITALIC LANGUAGES; ROMANCE LANGUAGES.

CELTIC. This group comprises (1) Cymric (Welsh, Breton, Cornish); (2) Gadhaelic (Erse, Manx, Gaelic). The literature can be traced to the eighth century A.D. See CELTIC LANGUAGES.

TEUTONIC. Originally Gothic (see GOTHIC LANGUAGE) and non-Gothic were the only divisions. These subsequently, on the basis of one euphonic change, were differentiated into Low and High German. The old divisions, still recognized by many scholars, are: (1) High German (Old, Middle, New); (2) Low German (Gothic, Saxon, Dutch, Frisian); (3) Scandinavian (Norse, Icelandic, Swedish, Danish). Gothic literature (translations of the New Testament) is of the fourth century A.D., but linguistic forms cited by Roman writers are earlier. See TEUTONIC LANGUAGES.

BALTO-SLAVIC (SLAVONIC). It is customary to unite these languages, which, however, stand as far apart as do Indo-Iranic. The Baltic (or Lettic) division, embracing the Old Prussian (q.v.), Lithuanian (q.v.), and Lettic (q.v.), the last-named spoken in Courland and Livonia, forms a unit over against the Slavic division (see SLAVIC LANGUAGES), which is divided into a large number of dialects incapable of being subdivided into different groups, though one division into Eastern, (South) Eastern, and Western, and another into two subdivisions are sometimes made. But phonetics and morphology together prevent such classifications except as a matter of convenience, all the dialects being more or less related, but not in such a way as to show that any of them formed sub-groups. A common and convenient geographical distribution is into the Western group, Polabian (formerly spoken in North Germany), Polish, Sorbian (represented by the Wendish spoken in Lusatia), Czechish (spoken in Bohemia, Moravia, etc.), and the (South) Eastern group, Servian, Croatian, Slovenian, Bulgarian, on the one hand, and Russian, on the other. Literary fragments go back to the eighth century. In the (narrower) Baltic division, however, a catechism of the sixteenth century represents the oldest known form of the dialect.

INNER RELATION. Having thus sketched the geography of these parts of the Indo-European languages, we must next inquire whether any of these parts hold to each other especially close relations. Much that here seems obvious shows itself to be misleading. Thus Latin is often regarded as standing in a peculiarly close relationship to Greek. In point of fact, however, while the Greek and Latin literatures are closely connected, there is no special kinship of the two languages. To detail all the groupings by subdivisions that have been urged by different scholars would take too much space, but the most practical historical differentiation is based on the varying treatment of the gutturals and vowels. In Hellenic, Italic, Celtic, and Teutonic, *k* and *q* represent the *ś* and *k* of the Eastern languages. The Sanskrit tenuis is preserved in the Western group, but the media and aspirate are modified to *j* and *h* (confused with the palatal evolution). The Western group had a pure *k* instead of the *ś*-series, and *q*-sounds (tending to become labials) instead of the *k*-series. Examples of the *k*-series are Hellenic *ἑ-κατόν*, Italic *centum*, but Indic *śatam*; *ὄχος*, wagon, but Avestan *vazaiti*: of the *q*-series, Italic *quod*, Indic *kad*. In vocalism the Eastern group has a simpler series than the Western. Now between these extremes lies the Balto-Slavic (and in part the Anatolic) system, which agrees with the Eastern group in having the *ś* and *k* series (as against the *k* and *q* series), but with the Western group in its more varied vocalism. There are no divisions of the languages which are of so marked a character as these of the '*śatam*' and '*centum*' divisions. Latin stands near to Celtic in some forms (future and passive), but near to Sanskrit in others (e.g. the ablative). So in other aspects of morphology, Balto-Slavic, Sanskrit, and Greek are akin, while in others they stand apart, and such resemblances and divergencies are found among the other languages as well. What the inner relation may have been cannot be more nearly established by a comparison of forms, still less of vocabulary, and it seems safest to establish as sub-groups only Eastern (Middle) and Western divisions. That Indic and Iranic lie so closely together may be due rather to their closer synchronism than to an originally greater similitude.

Before proceeding with the discussion of the inner relationship of these groups as shown by sounds, forms, and syntax, it is necessary to revert to the question of the primitive language, which, as was shown above, occupied so large a share of the attention of Schleicher. Since his day the problem has assumed a new form which may be studied under two aspects, geographical and dialectical. It was the opinion of the older Sanskritists that the earliest home of the Indo-Europeans was on the Pamir tablelands. Other sites have been assumed, the plains of Europe, Scandinavia, and many other centres. But on the basis of a comparison of the common vocabulary of all the languages and the state of culture represented by it, present opinion, induced largely by the results of Schrader's studies, inclines to the belief that the original home of the Indo-Europeans was on the plains north of the Carpathian Mountains. A very important contribution to the question was made by Schmidt, who tried to show that the duodecimal system of the Indo-Europeans was derived from Semitic sources. The discovery in 1902 of the Arzawa Letters (see above) would strengthen the belief in an early intercommunication between Indo-Europeans and Semites. These data, if accepted, would show that the Indo-Europeans at a very early period were near neighbors of the Semites, and perhaps in close communication with them. Further, it is known that trade communication between the north of Europe and the southeast, possibly Semitic, took place at an early date, and, finally, it is scarcely to be doubted that Indo-European language and Indo-European race are not terms implying an identity of race and language. In short, language proves nothing with regard to race. This truth leads to a clearer insight in regard to the 'parent speech.' Instead of imagining that there was a racial unity once marked by linguistic unity, we must inquire whether, in giving up racial unity as shown by language, we must not also renounce all attempts to establish a former linguistic unity. The answer will un-

doubtedly be an affirmative, and it is rendered more probable by all that we know of modern languages. The German dialects, for example, show no trace of ever having been identical in form. Still more striking is the illustration given by Slavic as compared with Baltic. In a word, there was no parent speech of the Indo-Europeans; but there were always related dialects. (See DIALECTS.) Thus the smallest dialect, geographically speaking, of Greece or Rome, may preserve forms as ancient as any other. The idea of a language-unity splitting up into dialects and these again into sub-dialects is a false conception. Co-dialectic forms is the only right expression. All efforts made to trace out a parent speech are based largely on doubtful data of the use of words regarded as original, although we do not know whether the words may not have been borrowed. All reconstructures of the parent speech, whether in the form of literature (such as Schleicher indulged in) or in the form of reconstructed hypothetical words, which are supposed to represent the sound of the *Ur-sprache* and are constantly employed in our comparative grammars, are pure fictions of the imagination, and are not to be regarded as representing an actual prehistoric condition of the language. We know the Indo-European languages only in dialectic form, as spoken by various races over a wide area. The dialects are divarications from each other, not, so far as we know, from any unitary parent speech. A universal parent speech is an historical possibility, but an Indo-European parent speech is merely a convenient hypothesis, which, however, leaves more to be explained than it explains, and may best be discarded, however pleasing it be to the mind which prefers unity.

PHONOLOGY. The regular interchange of certain sounds in the different languages of the Indo-European group was generally postulated at an early period without the later insistence on the necessity of regularity. At first it seemed as if there were exceptions which could not be explained by any law. The sounds first compared were consonantal, as these seemed most regular. Their correspondence in certain of the Indo-European languages was formulated by what is known as Grimm's law (q.v.).

The vowel-system took longer to explain and the consonantal system required modification. In the case of the vowels, apart from the determination of the long disputed point whether the *a*, *e*, *o* of the Greek, or their equivalents in one *a*-sound, as in Sanskrit, represented the older state, the vowel-system was seen to be more regular as soon as the primitive existence of sonant nasals and liquids was recognized. The chief modifications of Grimm's law and further contributary laws were established during the last quarter of the nineteenth century. At the same time was raised the question in regard to the original vowel-form of roots and that of its changes in *Ablaut* or modified vowels and diphthongs.

The priority of the Western *a*, *e*, *o*, as compared with the Asiatic monotone *a*, was proved by Amelung and Brugmann at about the same time. Next was shown the existence of an Indo-European *e*, that is of a real palatal vowel, in Sanskrit itself. This was proved by Collitz, and independently by Verner, through demonstrating that when a Sanskrit *a* (= *e*) follows a guttural it palatalizes it and hence must itself be palatal. Thus Sanskrit *ca* = *τε*, *quc*. Osthoff and Brugmann, again, pointed out the existence in Greek of the Sanskrit *l* and *r* vowels, as shown e.g in *πατράσι* (= Sk. *pitṛṣu*), *ἔδρακον*, etc. Then, as opposed to the view of the Hindu grammarians and early European scholars, it was shown that in the series *i*, *e*, *ai*, the simple vowel is no more radical than is the *guna* form, *e*, *ai*, or, in other words, we cannot speak of the stem in *φέυγω*, to take an analogous case, as being less original than that in *ἔφυγον*.

The chief modification of Grimm's law was made in 1875 by the complementary law of accent, which goes by the name of Verner's law (q.v.).

In discussing consonantism, the designations of other than the guttural series are self-explanatory, but in the guttural series there is great confusion of nomenclature. Thus the Indo-European languages had palatal sounds, *c*, *j*; dentals, *t*, *d*; labials, *p*, *b*, both aspirated and non-aspirated. So they had aspirated and non-aspirated, surd and sonant, gutturals, *k*, *g* (*kh*, *gh*). But these latter, being, as explained above, of twofold form, have different designations. There are two series, the palatal and non-palatal guttural series. These are sometimes distinguished as palatal and velar, but the former is also called the *ś*-series, and even the *k*-series; while the latter is called the *q*-series and also the *k*-series. The velar *k*-series was from the beginning distinguished from the palatal guttural by being a sort of back guttural, with a tendency to develop a half-vowel sound (*q*^{u} or *k*^{u}), which was lost in special languages. The two sounds either united or the guttural became more labialized, Sanskrit *ku*, Latin *quo*, Gothic *hva*, a tendency that reached an extreme in Greek, where this guttural is often represented by a labial, as in *πο* (also before nasals and liquids), though sometimes dentalized, as in *τε* (before *ι*, *ε*), while sometimes coinciding with *k* (*κῶς*). Besides gutturals and palatals, the Indo-European group possessed the consonantism just described, but it was defective in fricatives and spirants (e.g. *f*, English *th*, *z*). Peculiar to the older language are the aspirated sonants retained in the Indo-Iranic group beside aspirated surds, as well as the modified nasals and sibilants, *n*, *s*, including *m̥*, the final half-nasal, and final half-sibilant. As already explained, Indo-European had as half-vowels *y*, *v*, *l*, *r*. Lingual sounds (found in Sanskrit) appear to be borrowed from the Dravidians.

Before passing on to the subject of morphology it will be necessary to speak of one of the most important topics discussed, though not definitively settled, in the last few years. Verner showed that accent or stress influenced the character of consonants according to the accentuation of the syllable. The effect of stress, however, as already explained, is also patent as regards the vowel, which, as in *οἶδα*, *ἴδμεν* (originally *ἰδμές*), shifts with the accent. But of late it has been shown that another very important law of accentuation has been at work in determining the form of stems. Fick and Möller have emphasized the importance of pitch, that is, musical accent, as contrasted with stress accent. They show that there is a certain relation between the palatal vowel and a high pitch, and a guttural vowel and a low pitch, a relation explicable on physiological grounds: the action of the vocal or-

gans naturally associating the high pitch with the palatal *e* and the low pitch with the guttural *o*. Thus there is a natural connection between the accent or non-accent and the form of the two vowels in λεγω, the *e* vowel having the high pitch, the *o* vowel having the low pitch. This matter has not yet been thoroughly investigated, and there are many phenomena not yet explained by it. For example, in λόγος the low pitch has the stress. But at all events, accent is evidently a factor which will, when properly understood, explain much in stem-formation.

Morphology. This studies change of form and the cause of change. The chief factors tending to change the form of words are 'phonetic degeneration,' as it used to be called, or phonetic variation and growth, due partly to individual peculiarities, but more to the attrition of speech, force of expression, the law of least resistance, and the interaction of the individual and his environment. Change of stress and change of pitch and the substitution of stressed accent for pitch affect the form as well as the accent of words. Analogy (q.v.), especially false analogy, causes changes, in the endings particularly, and the growth or change of function in one class of words is liable seriously to affect the form and even the existence of words of another class. Imitation due to association may be conscious or unconscious. Complete changes in the pronunciation of a vowel may occur over a wide area in a short time and then remain, or as suddenly disappear. Most of these changes of form are the result of a long series of gradual minute alterations, intervening in time, both in phonetics and in morphology. Difference of meaning may be mentioned last as having had effect on form, a factor more or less connected with accent. Apart from these questions of the philosophy of change, morphology has to do with the forms as presented in language, which may most conveniently be discussed under the head of roots (see Roots), stems, the forms of nouns, and the forms of verbs.

In regard to the stem-complex of root and ending, apart from a vague theory of Westphal that 'near' and 'distant' sounds have something to do with stem-formation, only one theory has been opposed to Bopp's agglutination theory. This is a profound study by Ludwig, marred only by the assumption of absolute lawlessness in phonetics. The points made are that the endings serve different purposes, a first person serves as third, a locative as a genitive, etc., and the further back we go the looser is the language. Ludwig substitutes for agglutination, therefore, the theory of adaptation. Verbal endings are not from pronouns; no personal endings existed; before the verb was the indefinite infinitive used for any person, any tense, and both imperative or indicative in meaning; suffixes acquired definite implication by a gradual adaptation of special meanings, having originally only a demonstrative sense. While containing much truth, this adaptation theory is too exaggerated to be acceptable as a working hypothesis. Another theory, that of Scherer, regards endings of stems of verbs and nouns as indicating a locative sense, while Benfey traced all endings from *anti* (believing that nouns are from verbs); but the two latter views are too fantastic to be discussed.

Forms of Nouns. The same word is noun and verb in its most primitive form, as Sanskrit *dāti*, 'a giving' or 'he gives.' Nouns had seven cases, perhaps more, in Indo-European. The same case had different endings, but, on the other hand, it is most likely, despite the fact that this seems to point to other cases, that, had such cases existed, some traces would have been preserved. Different endings may gradually have become restricted in application, and, as in the case of the Greek dative, different functions may have been absorbed by one ending, tending to a loss of another ending. The seven cases have endings more or less uniform, but apart from modifications caused by the form of the stem, some cases are compounds of two case-endings and some cases show different forms according as a word is declined as noun or pronoun. The seven cases are nominative, accusative, instrumental, dative, genitive, ablative, locative. They are found in the singular, dual, and plural, but except for the nominative and accusative dual in *āu* (*dv-āu*, *duo*) the dual endings are not identical in the different languages and are omitted here. The vocative is not a case, but the bare stem in weak form. An apparent ending in the *o*-stems is only a vowel-weakening. The chief endings are:

Nom. sg., *s*, *m*; pl., *os* (*es*), (*o*)*i*, [*ā*].
Acc. sg., *m*, *d*; pl., *ms*, *ā*.
Instr. sg., *e*, *a*, *bhi* (*mi*), *na*; pl., *bhis*, *o-i-s*.
Dat. sg., (*ai*), *e*, *bhya*(*m*); pl., *bhyas*.
Gen. sg., (*o*)*s*, *sia*; pl., *om* (*ām*), *sām*.
Abl. sg., [*os*], (*a*)*t*; pl., *bhyas*.
Loc. sg., *i*; pl., *su* (*si*).

The ablative is lacking in the singular, except in a few nouns and pronouns, and in the plural, borrowing the forms of the genitive singular and dative plural. The plural *os* (*as*) is the noun-ending in Sanskrit; *ai* (*oi*) the pronoun ending in Sanskrit and Osean and the noun ending in Slavic, Greek, Latin, Celtic, and Gothic. As plural signs serve both *i* and *s*, the latter being added to the nominative, accusative, instrumental, and dative. Some endings were independent words, e.g., *i*, *u*, *a*, *āt*, and Sanskrit still has cases made by adding *ā* to *ē*. Adjectives have noun endings (with some restrictions). The comparative *tara* means 'farther' (also *ias*, *ios*). The superlative, *tata*, *tama*, and *ishta*, is not clear. Numerals have essentially the same form in Indo-European, *ai-ka* (*oinas*), *duā*, *tu*, *śatam-centum*, up to Χιλιοι = (*sa*)*hasra*, though the latter identification is doubtful, and in any case may mean 'heap,' or large number, rather than a definite thousand. The duodecimal system is clearly marked in Sanskrit higher numbers alongside of the decimal system (see above). Participles are part of the noun-system and the stems end in *ta*, *na*, *m*(*ā*)*na* in Sanskrit, Avestan, Greek, and Latin. Prepositions (adverbs) may have case-endings, e.g. παρα-*ί*, παρά, πρόσω.

Forms of Verbs. The Indo-European languages had four tenses, present (imperfect), aorist, perfect, future, and four modes, indicative, subjunctive, optative, and imperative. Only the first three tenses are pure, the future being modal (will), and consequently the future is found only in the indicative, with rare (Vedic) and late (Greek) exceptions. There are two voices, active and middle, the latter serving originally as a passive as well. Secondary conjugations of the pro-ethnic period are numerous. The most clearly defined are causative, denominative, intensive, desiderative, and inchoative. Sanskrit further invented a passive class, and Latin

and Celtic had a special passive voice, while Greek and Sanskrit converted certain aorist forms into passives. There are three numbers, but the dual is weak and even in the oldest Vedic and Greek interchanges with the plural, being lost in Celtic and Latin (save for the ending *-tis*), though preserved in Gothic and Balto-Slavic. Verbal endings are primary and secondary (present and preterite); special endings occur in the perfect. Omitting the dual, these endings in Sanskrit, which has preserved them most fully, are in the active singular, 1, *mi, a;* 2, *si, tha;* 3, *ti, a;* plural, 1, *mas ma;* 2, *tha, a;* 3, *a(n)ti, us;* while the middle changes *i* to *ē* and *mas, tha,* to *mahē, dhvē,* and the preterite tenses drop the final vowel and have *mahi, dhvam,* for *mahē, dhvē.* The preterites and the perfect have also certain *r*-forms, *ram, rē,* etc., like the Latin passive. The present stem is divided into many classes, of which ten are recognized by native Sanskrit grammarians. Including secondary conjugations, the Indo-European languages had in all thirty-two ways of varying the stem by infixes, suffixes, and changing the vowel of the root. Many of these verbal stems coincide with nominal stems. They appear originally to have indicated modified forms of action. The aorist stem is formed either by reduplication, like the perfect, or by inserting an *s*-element, like the future, or it may be differentiated from the present class merely by the vowel or by an ending (*βῆ, βάσκω*). The future has primary endings, but in Sanskrit may be augmented with preterite endings, making a conditional. The subjunctive and optative have different formative elements and their endings are originally the primary and secondary, respectively (see below), while the imperative has preterite endings modified, or special forms. It has no modal sign. In some classes of verbs the subjunctive form coincides with the indicative. Hence *ā*, the subjunctive modal sign, Greek *η*, is not locative, as Scherer taught, but probably due to analogy. The optative sign is *ia* when accented, *i* when unaccented, as shown by J. Schmidt; whence *i* is probably a reduction from *ia* (compare *yā*, 'go,' though this derivation is not favored by Schmidt).

As to the personal endings, with the exception of the third plural (and the dual), Delbrück thinks that they are connected with the personal pronouns, but if so they must go back to a period when they were more deictic than pronominal. The singular affixes *mi, si, ti* have been explained (not very convincingly) both as taken from the pronouns and as having originated the pronouns; but the plural *anti* is probably connected with the participle, the *i* being explained by Ascoli and Brugmann as due to analogy with *ti* (a locative in Scherer's opinion). This finite verbal form would then be analogous to *amamini* (also a participle). The middle endings have been explained as strengthened forms. In Sanskrit the only original strongest form is *āi* (*sāi* and *tāi* being later), a still stronger form of *ē*, which lends color to this (still doubtful) suggestion. Verbal stems were originally not connected with prepositions (most of which are adverbs); hence Latin compound verbs are later than Greek and Sanskrit, and 'tmesis' in the latter is really the older form. New forms have been developed in the separate language, e.g. aorist passives, the future optative and future infinitive in Greek; a third singular preterite aorist passive and a complete *ya*-passive in Sanskrit; *r*-passive and *bo*-future in Latin and Celtic. Greek, like Sanskrit, is older than Latin in having fuller endings, a middle voice, and an augment. The other Indo-European languages have later verbal forms. The augment may have had a short and a long form, *ε*, *η*, and survived in Sanskrit, Persian, and Greek, with traces in Avestan.

Syntax. Only the chief points can be noticed here. First, as to the syntax of nouns: The old distinction between grammatical and non-grammatical cases cannot be maintained. The nominative designates the active, the accusative the passive relation. The latter is both an object of a verb and an object of thought, *this day, me miserum*, non-verbal objectifications. With space and time the accusative is still a veiled object-case. The instrumental shows accompaniment, means, limit; the dative, 'to' or 'for;' the genitive, any adjectival relation, 'of,' 'belonging to;' the ablative, source and means, 'from,' 'by;' the locative, place or time, 'in,' 'at,' 'within.' The syntactical method of Delbrück assigns to each case a certain narrow function; as either 'in' or 'within' (but not both) to the original locative; 'to' or 'for' (but not both) to the dative, etc. But each (pure) case originally contained in itself all that is ascribed to it; the dative from the beginning was a 'to' and a 'for' case; the locative expressed both 'at,' 'in,' and 'within.' The instrumental survives in adverbial form in Greek, but the Greek dative singular is a locative. The genitive in *sia* is an adjective stem like that of the pronouns, *asmāka(m)*, *uostrum, nostri*, which explains in part the syntax of the case. So the Latin *ī*-genitive may be adjectival (preserved in other Italic dialects instead of changing to *oi* or *ei*, which would be the locative form). Other genitive syntax is explained as being due to a sort of adjective-compound effect, in that the sign *as* (*os*) is probably only a nominative affected by sentence accent. So *s* is the sign of the nominative as well as of the genitive. The ablative was probably confined at first to the singular pronoun, where it seems to be from an adverbial affix. Such syntactical growths are common, prepositions (adverbs) being affixed also to completed endings to emphasize the meaning, as *in* is added to the Italic locative, *ā* to the Avestan locative, or *i* to the Latin feminine nominative, *qua-i* (*quar*). In the last case the meaning is probably only emphatic, just as in English *yes-sir-ee, indeed-y*. The nominative *s* has been associated with the demonstrative pronoun. The *m* of the accusative is identical with the *m* of *abam, idam, ἑ-γών, idem*, though what shade of meaning it may have had is as impossible to explain, as is the pseudo-ending of the German *mich*. The neuter nominative in *m* has been explained as borrowed from the nominative, on the ground that neuters were originally not subjects of verbs; but this is improbable.

In verbs present tense-stem connotes durative time; the aorist, unrestricted time, either inchoative or resultant; the perfect, repeated present (inchoative or intensive); the future, modally affected future (will). The subjunctive gives the idea of the unrestricted indicative with the addition of a shall or will element (time and mode); the optative expresses

should or might; the imperative, a command. The aorist may be present or preterite in time and differs from the present-stem meaning only in its quality, since it does not express continued or durative time. Thus Sanskrit *gacchati*, present, is 'he continues a-going,' but *gāti*, aorist, is 'he goes.' The present may thus do duty for a future, as in Gothic. The verbal stem being coincident with the noun-stem, the sense of *bharati* is really 'a bearing, that' or 'he is a bearing,' rather than 'is a bearer.' The reduplication of the perfect connects it with the reduplicated present, desiderative, and intensive forms, and in its first application it connotes present time, afterwards extended to past time, perhaps helped thereto by the pluperfect (with augment), which in Sanskrit is not so much a pluperfect as a reduplicated aorist. The tense of narrative was originally the imperfect, not the aorist. The syntax of the Greek aorist is complicated by the confusion of aorist and imperfect forms. In Sanskrit, future (will and pure future) and optative complement each other and eventually suppress the subjunctive altogether.

The subjunctive, as already stated, has originally primary, the optative secondary endings; but in Sanskrit the former has taken some secondary endings, and in Greek the latter some primary endings. These endings are significant. The optative goes with the imperative and injunctive, modes of wish and command; the subjunctive with the future, shall and may. Delbrück believes that the subjunctive originally expressed will, the optative wish. But his categorical system of syntax is unable to explain the potential sense of the optative and the future sense of the subjunctive. The subjunctive originally connoted a vague shall-will, at the pleasure of the speaker. The primitive subjunctives, ἔδομαι, *ero*, are, in fact, simple futures. So the optative expressed both should and might. In Latin the subjunctive is partly optative. The Homeric subjunctive is later limited to half of its functions. Sanskrit has a distinct precative optative to express wish. Here, as elsewhere in grammar, linguistic machinery of a rough sort was slowly adapted to growing needs, and many shades of meaning were expressed under one form. Vulgar English shows continually how people without discrimination get along very comfortably with the same tense and mode and ending for many situations. In regard to the imperative, which has secondary endings, it was originally used only in the present and for commands, not for prohibitions. Hence μή is used with the subjunctive aorist, and later with the present imperfect only as an extension. So a subordinate negative clause takes μή, as ὅς μὴ ἔλθῃ, 'shall not come'). Thence the use was extended (οὐμή with indicative). Some scholars claim that the optative was originally potential, for the pure optative is used with οὐ, not with μή (for wish). It is worth noticing, in connection with the Greek secondary endings, that when used without augment they may always indicate a command, as in the Sanskrit injunctive, which is an unaugmented preterite.

The determination of the meaning of cases, of tenses, and of moods does not exhaust the store of syntactical problems upon which light has been thrown by comparative philology; but these are the most important aspects and they show sufficiently what has been accomplished. The discovery of new cases (instrumental and locative) in Sanskrit, not recognized in the classical languages, laid the basis for a thorough treatment of case-relations; as the discovery of the injunctive and the Vedic values of subjunctive, optative, aorist, and perfect first clarified the problems connected with the verb.

Modern Tendencies. A typical example of the relation between the stages of growth in the study of philology is given by etymology (q.v.). Before Pott there was an utter want of scientific method. Pott opposed this looseness. Curtius again opposed Pott for thirty years on the ground that Pott was not strict enough. The "young grammarians" in their turn attacked Curtius because he refused to admit that phonetic law is irrefragable.

More recent studies have made etymology much stricter still. To cite a famous example, of all the parallels in the names of Greek and Hindu gods utilized by Müller in his mythological studies, only one case, Dyaus-Zeus, is now regarded as certain. On the other hand, in the question of irrefragable phonetic law, the modern tendency has been to claim that the new school went too far. Bechtel, in 1892, and since then other scholars have questioned the validity of the shibboleth of 'changeless law.' Other doubts have arisen in the last decade on other fields. Stress accent has been replaced in part by musical accent in importance. Schmidt's wave theory has been modified. Semitic influence, as shown in numbers, has been replaced by a putative Dravidian influence, but this matter is unsettled. In geography, Lycian and Carian have been definitively removed from the field of the Indo-European languages. The importance and antiquity of Pali (q.v.) has been brought to the fore. The possibility of reconstructing a 'parent language' has been rendered quite doubtful. Syntax has virtually been built up by one great German scholar, Delbrück. It was the latest task of philology. Naturally the principles thus swiftly built into a system by one man are open to revision. Signs are apparent that the categorical method hitherto employed has ceased to be useful in helping to discover the genesis of syntactical change. Delbrück himself has admitted that his results are founded chiefly on subjective impression. Other scholars question, not the value of the facts amassed by Delbrück, but their interpretation, in criticism that began with Whitney and has tacitly been accepted by Brugmann, Speyer, and other interpreters of syntactical data. In like manner the motive of phonetic change as explained by Delbrück has recently been attacked by Wundt, Meyer, and Oertel, who have respectively sought to show that phonetic change depends largely on ease (or speed), strength of expiration, and geographical environment.

But besides laying stress on new points of view of minor importance, such as haplography, philology has recently brought to the fore one principle and elevated it into the dignity of a new branch of the study under the name of semasiology (q.v.). In 1897 Bréal published his *Essai de sémantique*, which organized into a systematic whole, under different categories, transfers of meaning in the evolution of words. Contiguity, resemblance, and contrast were shown to cause changes of meaning. Our word 'pike' for 'road,' for example, arose from 'turnpike road,' with a gradual reduction of the

phrase to its most characteristic element (the pike or pole which turned the stile at a toll-gate) to represent the whole.

PHIL'OMEL (Lat. *philomela*, from Gk. φιλομήλα, nightingale, from φιλεῖν, *philein*, to love + μέλος, *melos*, melody). A nightingale, especially the Persian one. *See* NIGHTINGALE.

PHIL'OME'LA (Lat., from Gk. Φιλομήλη). In Greek mythology, a daughter of Pandion, King of Athens, and sister of Procne. In reward for assistance rendered, Pandion gave Procne as wife to Tereus, King of Thrace, who became by her father of Itys. He then dishonored Philomela, pretending that Procne was dead, and to prevent her from telling her wrong cut out her tongue. Philomela, however, by weaving words in a robe, revealed the truth to Procne, who, to punish her husband, killed her son and served him up to Tereus. The sisters then fled, but, being pursued by Tereus, were changed into birds; Procne and Philomela to swallows or nightingales, while Tereus became a hoopoe or hawk.

PHILOMELA, THE LADY FITZWATERS' NIGHTINGALE. A romance by Robert Greene (1592). It is founded on an Italian story of jealousy, perhaps *Tito and Gisippo* in the *Decameron*. Philip charges a friend, Lutesio, to test his wife by tempting her. Though innocent, Philomela is divorced and flees to Palermo, where her repentant husband discovers her, but his joy is so great that he chokes and dies.

PHIL'OPŒ'MEN (Lat., from Gk. Φιλοποίμην, *Philopoimēn*) (B.C. 252-183). The most illustrious statesman and general of Greece in the period of her decline, the great object of whose life was to establish the independence of his country on a firm and lasting basis. He was born at Megalopolis, in Arcadia, of a noble family. At an early age he lost his father, and was brought up by a wealthy citizen of Mantinea named Cleander, who secured for him a careful education. He received instruction from the academic philosophers Ecdemus and Demophanes. His first experience in warfare was gained in the border raids which took place between the Arcadians and Laconians, and in B.C. 222 he with a few others defended Megalopolis against the attack of the Spartan King, Cleomenes. In the following year, when the Macedonian King Antigonus came to the assistance of the Achæans, Philopœmen joined him at the head of a band of horse, and distinguished himself in the battle of Sellasia (B.C. 221), in which the power of Sparta was completely broken. Philopœmen now went to Crete, where he lived for several years; on his return in 210 he was appointed commander of the Achæan horse, and in the expedition of 209 against Elis distinguished himself for his bravery, slaying with his own hand the Elean leader, Demophantus. In 208 he was chosen strategus or commander-in-chief of the Achæan League, a position which he held eight times in all. He at once proceeded to introduce reforms into the discipline and armor of the soldiers, and soon, by these means and by his personal influence, made the army a most effective instrument of war. In 207 he utterly defeated the Spartans under Machanidas, and at the Nemean festival which followed he was proclaimed liberator of Greece. In 201 he defeated Nabis, who had succeeded Machanidas as tyrant of Sparta, and soon afterwards made another voyage to Crete. Returning to the Peloponnesus in 194, he was appointed strategus in 192, and again defeated Nabis. Shortly after he compelled Sparta to enter the Achæan League, and when she revolted in 188 he took the town, razed the walls, and compelled her to adopt the Achæan laws. He was in his seventieth year and sick in bed when news was brought him that the Messenians had revolted from the League; he immediately left his bed and took command of the army. In the battle that ensued he was taken prisoner, and Deinocrates, the Messenian commander, sent him a cup of poisoned wine, which he drank. Consult: Plutarch's *Life of Philo-*

pedia). Freeman, *History of Federal Government in Greece and Italy* (2d ed., London and New York, 1893); Mahaffy, *Alexander's Empire* (New York, 1888).

PHILOSOPHER OF FERNEY. A title given to Voltaire, from his Swiss residence.

PHILOSOPHER OF MALMESBURY. A title conferred on Thomas Hobbes, from the name of his birthplace.

PHILOSOPHER OF SANS-SOUCI, sän sōō'sē'. A title applied to Frederick the Great.

PHILOSOPHER OF WIMBLEDON. A name used of John Horne Tooke, from his residence in Surrey.

PHILOSOPHER'S STONE, The. A mysterious compound to which was attributed the power of transmuting metals into gold or silver, and the attempted making of which was the chief occupation of alchemists, at least during the Middle Ages. In reality it bore no resemblance to a stone, being more properly described as an amalgam. It was a universal panacea that was so eagerly sought, for with the function of a universal solvent it combined that of the elixir of life, a renewing influence on the body. The conception of the transmutation of metals was Oriental. The Arabs regarded metals as compounded of mercury and sulphur in varying proportions. To this was added a more philosophic conception of a common basis of all forms of matter, individual forms being due to a force separable from this. If the 'materia prima' could be dissolved from the combining forces and united with the special 'form' of gold and the combination could be controlled, then any bodies could be produced at will. Three forms of the philosopher's stone are mentioned: the great elixir, a red tincture transmuting metals into gold; the elixir vitæ, restoring youth and prolonging life; and the lesser elixir, a white tincture, changing metals into silver. The powers of the philosopher's stone appear to have been first described by Zosimus in the fifth century. Geber (q.v.) was the reputed author of the *Key of Wisdom*, a secret book on the philosopher's stone. The matter was generally shrouded in mystery and not clearly defined until the twelfth century. Salt, sulphur, and mercury, regarded as the elements of matter, were combined to produce the solvent. By the sixteenth century the formula of preparation had become more definite. The 'mercury of philosophy,' combined with gold, was placed in a furnace where the gold was dissolved. After a long interval a black powder, called Saturn, was produced. A further heating produced the white tincture, or little philosopher's stone, and a hotter fire produced a red powder, the true stone. Van Helmont asserted that he had seen and handled the stone, which was sulphur color, heavy, and brilliant as glass. Paracelsus described it as a solid of deep ruby color, transparent, flexible, and brittle as glass; Raymond Lully, as a carbuncle. After the thirteenth century a mystic and esoteric interpretation of the philosopher's stone seems to have been applied to metals, the stone bringing to the wearer wisdom and virtue, and purifying the soul.

PHILOSOPHICAL SOCIETY, American. The oldest of American learned societies. Its official name is the American Philosophical Society, Held at Philadelphia for Promoting Useful Knowledge. Its hall is No. 104 South Fifth Street, Philadelphia, in which are meeting and banquet rooms, an extensive and valuable library, many interesting portraits and busts, one of the latter being Houdon's Franklin, and a collection of relics, including the chair used by Jefferson while writing the Declaration of Independence. In 1893 the society celebrated the sesqui-centenary of its beginning, for on May 14, 1743, Benjamin Franklin published in Philadelphia "A Proposal for Promoting Useful Knowledge among the British Plantations in America," and though his suggestions were not acted upon immediately, he wrote on April 5, 1744, that the society had been formed and had held several meetings, with Thomas Hopkinson as president and himself as secretary. Within a few years regular meetings were discontinued, though before 1758 another society was started in Philadelphia, called the Junto, or Society for the Promotion of Useful Knowledge, which also languished until April 25, 1766, when it was revived, with thirty members, as the American Society for Promoting and Propagating Useful Knowledge. The earlier society renewed its activity in November, 1767, and the union of the two was suggested, but a year was spent in negotiation before the two became one on January 2, 1769, adopting the present name and electing Benjamin Franklin president. He held this office until his death in 1790. The second president was David Rittenhouse, the astronomer and the first director of the United States Mint, and he was succeeded by Thomas Jefferson. In 1785 John Hyacinthe de Magellan, of London, presented two hundred guineas to the society for a perpetual fund, the interest each year to be put into a gold medal, to be given to the author of the best discovery or improvement in navigation, natural history, or astronomy. The Magellanic fund has always been kept as a separate investment, and its medal is considered one of the great honors in the scientific world. Membership in the society is limited to those who are invited to join on account of their contributions to science and knowledge; consequently the honor of an election is highly prized by American scientists. In recent years the society has established a series of annual meetings, to which distinguished men of science of Europe are invited, and these assemblages have become events of international interest. The published *Transactions* of the society begin with 1771, in which year a copy was given to each member of the General Assembly of Pennsylvania, with the statement that "the volume is wholly American in composition, printing, and paper." The society also publishes *Proceedings*, beginning in 1838, issuing them in about two hundred parts, making over forty volumes.

PHILOSOPHY (Lat. *philosophia*, from Gk. φιλοσοφία, love of knowledge, from φιλεῖν, *philein*, to love + σοφία, *sophia*, wisdom, from σοφός, *sophos*, wise). A term originally used, e.g. by Socrates, to mean devotion to the pursuit of truth. In Plato it came to mean knowledge of eternal reality. Aristotle employed the term sometimes as equivalent to critical systematized knowledge, sometimes as meaning the science of ultimate reality. The Stoics considered philosophy to be the endeavor to obtain excellence

(ἀρετή, *aretē*) in knowledge and in morality; the Epicureans regarded the philosopher as the man who pursued happiness in the manner suggested by reason. In the Middle Ages philosophy came to be ancillary to theology, and in large measure the reasoned defense of divinely revealed truth. In modern times various definitions have been given, such as "rational knowledge derived from concepts as such" (Kant), "the revision of concepts" (Herbart), "the science of principles" (Ueberweg), "the totality (*Inbegriff*) of all scientific knowledge" (Paulsen), and "the reduction of the general knowledge obtained by the special sciences to a complete system" (Wundt); while some thinkers have despaired of the possibility of finding any definition that shall cover the whole field historically occupied by philosophical speculation. The conception of the task of philosophy necessarily changes with the course of time. At the beginning, before any special sciences had arisen, it was natural that the unity of knowledge should be insisted on, and that the student should ambitiously take all knowledge for his province. But the scope of philosophy has gradually grown narrower as its original domain has been encroached upon by new sciences. The failure of philosophers of the present to agree on the definition of their work is due to the fact that so much territory has been already occupied by these sciences as to leave the proper domain of philosophy in doubt. These sciences have one and all been experiential in their method. To those who believe in the existence of *a priori* knowledge, a point of departure for delimiting philosophy from science is obtained in this distinction of the inductive from the deductive. But the belief in *a priori* knowledge is less current than it was a hundred years ago, and some other differentiation of philosophy from science must be undertaken by the inductivist. Perhaps no better plan can be adopted than that based upon the specialistic character of present-day science. Each science pursues its own investigations in its own limited field, and will allow itself to be prejudiced as little as possible by what is done in other fields. But after all it is the same universe that furnishes object-matter to all the separate sciences, and one would naturally expect that all the separate knowledges gained by specialists would articulate themselves into a coherent system of knowledge. The hope to accomplish this articulation in detail would be idle; but every science has its concepts, which it uses to organize the facts in its own little field. Do all the concepts tally? Are they compatible with each other? Questions of this sort are reasonable, and an attempt to answer them forms the so-called philosophy of nature, which may be defined as the correlation and criticism of scientific concepts. Among such concepts are those of matter, energy and its conservation, atom, life, evolution, differential, point, line, etc. The philosophy of nature is without doubt the most difficult branch of philosophy, as it demands for its prosecution considerable familiarity with the leading sciences. But while it is not to be hoped that any very general treatment of the subject can be satisfactory, still more detailed work in the way of correlation and criticism of the conceptions employed in a few sciences can be reasonably expected. Such work has been done in English by Stallo in his *Concepts and Theories of Modern Physics* (London, 1882), and by James Ward in his *Naturalism and Agnosticism* (London, 1899).

Again, all the sciences take for granted that man can know something about the universe. What is this knowledge? Is it really valid, as it claims to be? Is there any way of ascertaining its validity? A scientific treatment of these questions is called epistemology, or the theory of knowledge (q.v.), and forms a second philosophical discipline. Still again, can any light be thrown on the ultimate nature of the reality either of the external world or of the mind? This is the problem of metaphysics (q.v.). Formerly logic, psychology, and ethics were considered as branches of philosophy, but the modern tendency is to establish them as separate sciences. This is accomplished, however, only in a restricted sense. At bottom the question whether this or that discipline is a science or a branch of philosophy is of no great importance, when it is recognized that there is no fundamental difference in method between science and philosophy, the only difference being one of degree, not of kind. The more abstract any systematic knowledge is, the narrower the field it appropriates to itself; the more it neglects other subjects lying outside of that field, so much the more properly is it called a special science. On the contrary, the more comprehensive such knowledge is, the more philosophical it is: for philosophy is an attempt as far as possible to know the world as a whole.

History. The history of European philosophy is commonly divided into three main epochs, each characterized by a unique development, although at the same time the earlier periods furnish preface and starting-point for those which succeed them, so that the whole development is continuous. The first of these periods is that of ancient or Greek philosophy (q.v.). It extends from the earliest formulations of philosophic conceptions among the Ionian philosophers and continues into the Christian Era, throughout the dominance of paganism. While shared by other nations of antiquity besides the Greeks, as notably by certain Romans, Jews, and Græco-Egyptians, it received its form and lasting bent from the Greek mind, and its later influence proceeds almost exclusively from Athenian culture. The second period is that of mediæval philosophy, or scholasticism (q.v.). It had its rise in the theological speculations of the early Church Fathers, usually educated in Greek thought, and was continued and developed throughout mediæval times as the characteristic philosophy of Catholic Christianity. It had its culmination in the great synthesis of Thomas Aquinas, but has never ceased to be the traditional philosophy of the Church, and in modern times, as neo-scholasticism, is the subject of an energetic revival. During the scholastic period in Christian Europe the tradition of Greek philosophy was kept alive by the Arabs in Spain (see Arabic Language and Literature), among whom were many important philosophical thinkers. The third period is known as the period of modern philosophy, and is commonly dated from the Renaissance (q.v.), and more particularly from the advocacy of empirical methods of investigation by Bacon and of appeal to immediate reason or intuition by Descartes.

With the revival of learning there was also a

revival of all the important philosophical systems of antiquity. Platonism flourished in the Academy of Florence and found its most important advocate in Ficino. Neo-Platonism blended with Neo-Pythagoreanism which was represented by Pico della Mirandola. Aristotelianism renewed its vigor in the two rival schools of Averroism and Alexandrism, and among the Protestants in Melanchthon. Skepticism was defended by Montaigne, Sanchez, and Charron; eclecticism, virulent in its opposition to scholasticism, was propagated by Valla, Vives, de la Ramée, and Zwingli, while scholasticism found its champion in Suarez. Natural philosophy, a rehabilitation of one phase of Aristotle's system, but blended with Neo-Platonic mysticism, was developed by Cardano, Campanella, and especially by Bruno. Paracelsus and Böhme elaborated the mystical side of this line of thought, while Galileo and Kepler remained more true to an empirical study of nature, and formed the starting point of a mechanistic and materialistic conception of the universe. In Kepler, however, with his insistence on the harmony of the world order, we have a distinctively Pythagorean touch. Political philosophy took an entirely new start with Machiavelli, who threw aside the work of Aristotle and the authority of the Church, and worked out an anti-moral theory in which the State and civic freedom were all-important. But though the philosophers of the Renaissance thus bridged over the chasm that separated the ancient from the modern world of thought, it was reserved for Bacon and Descartes to lay the foundations of modern philosophy in empiricism on the one hand and in rationalism on the other; and the real problem of modern philosophy has been to rear a superstructure which should rest on both these foundations. As was to be expected, the foundations had first to be laid independently, and as a result we have two great modern schools, each equally one-sided, but each equally standing for a fundamental truth—the one, the truth that all secure knowledge rests on experience; the other, the truth that in all satisfactory knowledge the demands of reason are met.

Modern empiricism came to articulate expression first in Francis Bacon, who insisted upon the abandonment of the deductive, *a priori* speculation of the schoolmen, and on the necessity of studying nature without bias. Hobbes followed Bacon in urging the necessity of a philosophy of experience; but being especially interested in human nature, and yet lacking the data for an inductive study of society, he allowed himself to construct society out of imaginary isolated human beings and to palm off this fiction for fact.

Modern rationalism began with Descartes, who is often called the father of modern philosophy. He likewise emphasized the necessity of beginning anew, but, unlike Bacon, he looked to the inner nature of self-consciousness for the principles that can build up the structure and furnish the certainty of knowledge. The Cartesian system is rationalistic; the method for advancing our knowledge was thought to consist in letting the light of reason shine forth. This was accomplished by the application of mathematical method to metaphysics, with the result of bringing out the innate truths and principles of reason. In this way we become assured, Descartes argued, of our own existence, of the existence of God, and of that of the material universe. Descartes sharply separated mind and matter; mind is thinking, unextended substance; matter is unconscious, extended substance. Two great problems are therefore handed down to his immediate followers. What is the relation between mind and matter in general, and the soul and body in particular? And what is the relation between the soul and God? Geulincx, the founder of Occasionalism (q.v.), answers the former question by saying that God acts in the individual, intervening on each occasion, to maintain the parallel between mind and body. God is the real subject of human acts, the individual being but a nominal subject. The second problem is taken up by Malebranche, who maintains that God thinks in the individual. The individual is nothing but the mode of God's being. The mind is in God, and in Him views everything in its eternal significance. Spinoza carries out Cartesianism to its logical conclusion. Substance is that which exists independently. Hence the infinite alone, God, is true substance. Mind and matter are two attributes of the one divine substance. They are known to us as the parallel manifestations of the hidden substantial identity in God. Spinoza develops his system by pure deductive reasoning, following the procedure of geometrical demonstrations. He thus exhibits the ideal method of rationalism, which regards reason, working solely on its own inner principles, as capable of discovering the true nature of reality. The moral and physical parts of the universe follow from these principles with the same rigid necessity as the *demonstranda* of geometry follow from its axioms. Joyful resignation to this rationalistic determinism is the essence of morality. Spinozism reduces the dualism of mind and matter to a common principle and results in pantheistic monism (q.v.). Leibnitz endeavors to solve the paradox of Spinozism that unextended and extended substances are ultimately identical. As a rationalist he sides with Spinoza; as an individualist he sides with Locke. Leibnitz's substance is not that which *exists* through itself, but rather that which *acts* through itself. Reality consists of an infinite number of monads (q.v.), which are unextended, ideal activities, centres of original forces, or *formal* atoms. Each atom is self-contained and cannot be modified from without. Spinoza surrenders the reality of individuals to the principle of unity. This unity Leibnitz breaks up into a plurality of independent, self-active monads. But the multiplicity is synthetized by the Leibnitzian principle of continuity and the law of preëstablished harmony (q.v.). All the monads belong to an organized system, and each mirrors or represents the universe. The individuals are not isolated, but belong to an organic whole. God, the supreme monad, is pure activity, while finite monads are in a state of imperfect realization. They are not completely active. It is the passivity of finite monads that gives rise to confused perceptions, which cause the appearance of an extended, material world. These fundamental principles of Leibnitz's system are sacrificed by his follower, Wolff, who adopted merely the rationalistic method of his master and reduced philosophy once more to scholastic form. This was the culmination of dogmatic rationalism on the Continent.

In the meantime the empiricism begun by Bacon and the rationalism begun by Descartes became curiously intermixed in Locke's theory of knowledge. Locke supported the Baconian appeal to experience. The sole sources of our knowledge are empirical facts, since the mind has no innate ideas. All the materials of knowledge are externally impressed upon the mind, the sole activity of which consists in linking together the given ideas. Upon this sensationalistic basis, however, Locke built up a rationalistic ideal of knowledge. We attain certainty in our intuitive knowledge of the existence of the self, and in the demonstrative knowledge of the existence of God, and of mathematical and moral truths as well. Our knowledge of the external world, being dependent upon sense-perception, reaches only the level of probability. In this, Locke violated his own fundamental principle that our knowledge extends no further than our sensationally given ideas, and that truth consists in the agreement of ideas among themselves, not in their correspondence with things or external reality. Berkeley took Locke's definition of knowledge in a strict sense, and insisted that we never get beyond the circle of our own ideas. We know nothing about the agreement of our subjective ideas with external things. All knowledge, he contended, is purely individual, and all ideas are merely particular. The mistaken belief in the existence of self is due to the confusion of taking an abstract or general name as representative of a real thing. The reality of sense-objects consists in their being perceived. The assumption of an object apart from the idea is as useless as its existence would be. Ideas signify nothing but modifications of the conscious subject. Hume carried empiricism to its inevitable logical consequence. There is nothing knowable, he argued, but conscious experiences—'impressions' and their copies, 'ideas.' These we cannot transcend. They are externally connected by 'gentle forces,' called relations or associations. We cannot prove the existence of God, of the self, or of matter. All these are fictions of the imagination, and have no basis in actual experience. Thus, step by step, empiricism ends in skepticism.

Kant, the founder of the critical philosophy, consciously and critically attempted what Locke had naïvely achieved, the arbitration of the controversy between empiricism and rationalism. His decision was that rationalism is right in its determination of scientific method: empiricism, in limiting scientific knowledge to the sphere of possible experience or phenomena. Knowledge, he maintained, is a joint product of two factors, one furnished by the conscious subject, the other given in the raw material of sensation. The former is *a priori;* it antedates experience and is the condition which makes experience possible. The latter is *a posteriori*, given from without. The *a priori* would be devoid of content without the sensible material; the *a posteriori* would be nothing at all were it not shaped and transfigured in the mold of consciousness. Theoretical reason may not transcend the bounded domain of experience, but practical reason asserts the necessity of the belief in a world of transcendent reality, in which the moral order is the natural law. God, freedom, and immortality, though undemonstrable, are the necessary postulates of our moral being. Thus reason gives way to faith. Fichte, starting from a Kantian basis, objected to Kant's failure to show how the *a priori* principles of consciousness are necessarily involved in the nature of consciousness, as well as to the Kantian separation of the phenomenal world and the real world of things-in-themselves. By exhibiting the process in which consciousness unfolds itself, we see that the phenomenal world is meaningless unless organically connected with its intelligible essence. Knowledge is neither in whole (Hume) nor in part (Kant) the product of sensation. It is the creation of the ego. Voluntary selves freely choose to assert themselves and thus construct their whole organized world. The moral law is the prior condition of all we theoretically know, and the outer world exists simply for the sake of our moral self-realization. The speculative method, the exhibition of the progressive nature of consciousness, is the only possible method, since knowing does not begin with facts passively received by the ego, but with a spontaneous act of the ego's creative energy. Jacobi also objected to the Kantian separation between the thing-in-itself and the phenomenal world. Without the thing-in-itself, he said, no one can enter the Kantian system, and with it no one can remain in that system. The only solution of this antinomy was to exalt faith, to which even Kant had recourse, to the supreme place in philosophy. Not knowledge, but feeling, is the organon whereby we can attain certainty of reality. Thus results a philosophy of supranatural sensualism. Schelling reached much the same result, but by a different method. He regarded the world as the embodiment of intelligence, an objective fact, indeed, but one that exhibits in its progressive forms the same principle that is found in man. But the character of that absolute principle which thus manifests itself in external nature and in man cannot be apprehended by reason. Intuition alone brings us into contact with ultimate reality. In Hegel German rationalism vigorously reasserted itself: the real is the rational and the rational is the real. All reality is but a manifestation of reason. The world is a development of thought. But thought and reason are not abstractions. The word thought is used with a width of meaning that includes in it the concrete content of the world of sense organized into an all-inclusive universe. The life and stir of the universe is the life of thought. The development of this concrete thought is a dialectical development, hence philosophy must employ the dialectical method to exhibit the nature of reality. The motive force of this development is opposition and negation. Everything is what it is by virtue of what it is not; that is, by virtue of its relation to other things. These various things taken apart are self-contradictory; only when seen in their interconnection are they seen to be real. The contradictories are not annulled in their mutual relations; they are conserved, but thus conserved no longer are they contradictory. The tracing of this process of negation is the Hegelian dialectic. With the death of Hegel, Hegelianism broke up into warring schools and became utterly discounted in Germany, only to be resuscitated later in England and America in the so-called Neo-Hegelian School.

Schleiermacher took up the philosophical problem where Fichte, Schelling, and Jacobi had left

it. He agreed with Jacobi that thought cannot grasp the essence of reality; hence philosophy is not a complete science; but while it is not complete, it is ever growing and reaching out toward the goal of the identity of thought and being. This goal, however, can be reached only in religion, the communion of the finite with the infinite upon which it feels itself dependent. In Herbart and Schopenhauer there is a twofold opposition to Hegelianism; the former opposed his doctrine of real qualities to Hegel's idealism; the latter directed his pessimism (q.v.) against the idealistic estimate of the value of existence, and maintained that the real is an irrational principle of blind impulse. Beneke attempted to synthesize the results of previous philosophical activity by developing a psychological philosophy, based on inner experience. Self-consciousness reveals directly to us the psychic constitution of man; sensation is only mediate knowledge of the outer world, which must be interpreted after the analogy of psychic life. Lotze combined the Hegelian and Herbartian positions, while Hartmann aimed at a synthesis of Schopenhauer and Hegel. Among recent German thinkers the cry of "Back to Kant" is especially prominent; this Neo-Kantianism is represented by such men as Lange, Cohen, Volkelt, Riehl, and Paulsen. Another vigorous German school at present is that of the so-called immanent philosophy of Schuppe, Rehmke, and Schubert Soldern, who deny the antithesis of idea and object, and assert an identical unitary consciousness in all beings. The immanent content of this consciousness is the world of space and time. Allied to this immanent philosophy is the empiriocriticism of Avenarius, who, like Schuppe, begins, not with the opposition of subject and object, but with the pure experience of the unsophisticated man free of all preconceived theory. In this experience the so-called object of consciousness is an integral part; and of this experience philosophy is an exact description. Materialism had a temporary revival in the middle of the nineteenth century in Germany; its champions were Vogt, R. Wagner, Moleschott, Büchner, Czolbe, and Dühring. Sometimes identified with materialism is the monism of Haeckel, who, however, is not a materialist, but an animist, holding all matter to be instinct with life; but inasmuch as the material, not the conscious, side of being is emphasized, the doctrine is closely allied to materialism. Fechner had some years before Haeckel advocated an animism, which, however, had emphasized the conscious side of being. Wundt's philosophy is related to Fechner's, inasmuch as he holds that the mechanical universe is "the outer wrapper behind which is hidden a spiritual creative activity, a striving, feeling, sensing, like that which we experience in ourselves." Holding that conation is the most fundamental essence of this activity, his view is voluntaristic.

Returning now to French philosophy, we may say that after the time of Descartes there have been no epoch-making thinkers in France except Rousseau and Comte. Deserving of mention are Bayle, the skeptic; Voltaire, more positive in his attitude and with a leaning toward mechanism; Rousseau, the political philosopher, believing with Hobbes in a state of nature preceding society, but emphasizing the social nature of man, which Hobbes had ignored; La Mettrie and Condillac, sensationalists; La Rochefoucauld and Helvétius, egoists; Bonnet, a rationalistic sensationalist; Diderot and d'Alembert, pantheists. The last three, along with minor thinkers, are known as the Encyclopædists, because of their coöperation in the issue of the great *Encyclopédie*. During the French Revolution the predominant philosophy was sensationalism, going under the name of ideology, given it by Destutt de Tracy. Cabanis emphasized the physiological basis of sensationalism; a little later Maine de Biran, starting with the psychological fact of self-consciousness, reached a view similar to Beneke's, in which the spiritual nature of self-activity received recognition. He was thus the forerunner of spiritualism (q.v.), which was championed by Jouffroy and Royer-Collard, and had in Cousin its most prominent exponent. Spiritualism lived through the nineteenth century, being later represented by Ravaisson, Secrétan, and Vacherot. Opposed to ideology were the traditionalists, who, while reaching spiritualistic results, were hostile to the method of the spiritualists. Accepting the Catholic doctrines as unimpeachable, they emphasized the supremacy of faith above reason. Reason inaugurated the Reformation and issued in the Revolution; it is the source of nothing but evil. Faith resting on inspired authority is alone able to reach the truth. So wrote De Maistre, Frayssinnous, and Bonald. But reason would not down, and turned its attention to the social nature and relations of human beings. Saint-Simon, the founder of the French Socialistic School, was not himself so much a philosopher as a reformer; he practiced rather than theorized; but he interested many speculative minds in social problems. The greatest of his disciples was Auguste Comte. Comte contended that the only true and final philosophy is positive; true philosophy is an accurate description of facts and their experienced relations. He brushed aside all pretence of knowledge of anything more ultimate than the phenomena of experience. Positivism, however, according to Comte, is only the third stage of philosophical reflection. Man's first attitude toward nature was theological; he attempted to explain phenomena by referring them to supernatural powers. Then man became metaphysical, using abstract conceptions, like force, as principles of explanation. Finally as the third stage came positivism, the insight into the futility of previous explanations, and the recognition of facts and their relations as philosophical ultimates. About the middle of the nineteenth century, in protest against Comte, a revival of Platonism occurred in certain Catholic circles; Cartuyvels, Huguin, and Gratry maintained that ideas are modes of God's essence. Positivism passed over into agnosticism in Littré, Taine, and Renan. With the development of experimental psychology a psychological philosophy has been cultivated by Ribot, Delbeuf, and Bernard. After Darwin's *Origin of Species* appeared, evolutionism was eagerly taken up by French thinkers, chief among whom have been Fouillée and Guyau. But Kantian principles maintained their ground in the philosophy of Renouvier and his followers. Lachelier attempted a combination of Kantianism and spiritualism. Against the determinism (q.v.) of positivism, psychologism, and evolutionism, Boutroux advocates a philosophy of contingency and freedom.

Since Bruno's time Italy has made little original contribution to philosophy, although she can boast of many brilliant expositors of already existing systems. Vico and Beccaria can lay the best claim to originality, both working in the realm of the philosophy of law. Genovesi, the empiricist; Galluppi, the sensationalist; Rosmini and Gioberti, objective idealists; Mamiani, a modified Platonist; Vera and Spaventa, Hegelians; Testa and Cantoni, Kantians; Villari and Dominicis, positivists; and Bonavino, Thomist, deserve passing mention.

For the last two centuries Great Britain has shared with Germany the honor of having distinctive national philosophies. English thought has been predominantly empiristic and associationistic until the last half century. Hartley gave associationism (q.v.) its modern form, and James Mill applied it to all the life of mind. John Stuart Mill, best known popularly by his utilitarianism (q.v.), did his greatest philosophic work in logic. True to empiricism, he introduced induction into the place it now occupies in logical theory, and yet he builded better than he knew. His empiricism did not furnish an adequate basis for his logic, and subsequent logicians, as Sigwart in Germany and Bosanquet in England, have succeeded in effecting a reconciliation between empiricism and rationalism in logic; but this they could not have done without Mill's pioneer work. Darwin's great discovery has been extremely fruitful in philosophy. Spencer has worked out an evolutionary philosophy in elaborate detail, but with a strong individualistic bias. It is, however, marred by a lack of historic perspective. Lewes represented positivism; Martineau has been the most prominent advocate of intuitionism (q.v.), applying intuitionistic principles especially to ethics and theology. Green, Bradley, and Bosanquet, under the influence of German idealism, have sought to stem the tide of empiricism. Ward, from a psychological starting-point, has likewise reached an idealistic result. Under the leadership of these men and of the two Cairds, of Scotland, English philosophy has almost left its empiristic moorings.

The typical philosophy of Scotland since the time of Hume has been intuitionism. Hutcheson may be regarded as its founder. Reid and Stewart gave it classical expression. This Scotch thought was a protest against the Lockean doctrine that knowledge is only a correspondence between ideas, and stoutly maintained that we have immediate knowledge of objective reality. Hamilton, in his natural realism, sought to reconcile intuitionism with Kantianism. The two Cairds and Stirling broke away from the intuitionistic tradition and gave Hegelianism a vogue which makes it rival intuitionism in Scotland and empiricism in England.

In America the greatest original philosopher was Jonathan Edwards, who, starting from Lockean premises, elaborated under Calvinistic influences a most uncompromising determinism (q.v.). Franklin, while not technically a philosopher, gave an impetus toward empiricism. Witherspoon and McCosh brought strong support to Scotch intuitionism, also taught by Upham and Wayland. Among the educators who early aroused interest in philosophy were Noah Porter, Mark Hopkins, and Daniel Coit Gilman. Hickok was mildly Kantian; Bowen was eclectic; Bowne and Ladd are Lotzeans. The Concord School of Philosophy, headed by Emerson, popularized German idealism, which has been strongly defended technically by Harris; while Royce and Dewey have given it a more independent and original statement. James is a brilliant advocate of empiricism and seeks to rescue philosophy from agnosticism by asserting the right of a will to believe in face of doubt; and George Stuart Fullerton is a keen critic, whose studies in epistemology are of special importance.

In the last century the significance of the history of philosophy has been brought out by a long line of historians, beginning with Hegel. The result is that the continuity of philosophic development, and the genuine advance made by philosophic thought, in spite of an apparently merely back-and-forth movement, have been appreciated.

PHILOSOPHY, MORAL. See ETHICS.

PHILOS'TRATUS (Lat., from Gk. Φιλόστρατος). The name of four sophists of the Roman Imperial period. According to Suidas the first three were all natives of the island of Lemnos. (1) The first PHILOSTRATUS lived in Nero's reign (A.D. 54-68). The only extant work of his is the dia-

logue *Nero*, a conversation between the Lemnian Mnesicrates and the banished philosopher Musonius Rufus on the Emperor's proposed canal across the Isthmus of Corinth and on his great cruelty. (2) FLAVIUS PHILOSTRATUS flourished under Septimius Severus (A.D. 193-211) and his successors. At the request of the Empress Julia Domna, he wrote a remarkable *Life of Apollonius of Tyana*, in which he laid especial stress on the miracles ascribed to this pagan saint. The work was used later to oppose the teachings of the Christians. The same Philostratus is the author of the extant *Lives of the Sophists*, written soon after A.D. 229. (3) The third PHILOSTRATUS, son of Nervianus and son-in-law of Flavius Philostratus, was a young man in the reign of Caracalla (A.D. 211-217). He composed a work entitled *Imagines* (Εἰκόνες), which is still extant and describes 64 paintings in Naples. (4) The last PHILOSTRATUS was a grandson on his mother's side of the third Philostratus. He also wrote an *Imagines*, after the manner of his grandfather's book. This work is inferior to its model, and in its present form breaks off in the description of the seventeenth painting. The *Imagines* of the third Philostratus at least have now been proved to be descriptions of actual works of art, and so are of great value to the archæologist. The dialogue *Heroicus* probably belongs to the third sophist, while the second apparently was the author of the interesting collection of *Letters*. The standard edition of all these works is by Kayser in the Teubner Collection (2 vols., Leipzig, 1849). The *Imagines* of the third Philostratus have been separately edited by the members of the Vienna Classical Seminary (Leipzig, 1893).

PHILO'TAS (Lat., from Gk. Φιλώτας). A Macedonian general. See PARMENION.

PHILOXENIAN VERSION. See BIBLE, section on *Text of the New Testament*.

PHILOX'ENUS (Lat., from Gk. Φιλόξενος) (B.C. 435-380). A famous dithyrambic poet, born in Cythera. When the Spartans recaptured the island from the Athenians, probably after the Sicilian Expedition, he became a slave. Eventually he passed into the hands of the poet Melanippides, who, attracted by his talent, educated and freed him. He lived some time at the court of the elder Dionysius in Syracuse. There he forfeited the tyrant's friendship either on account of his frank criticism of his patron's verses or because of his love for a beautiful flute-player, Galatea, the mistress of Dionysius, and was imprisoned in the quarries. Philoxenus subsequently took vengeance on Dionysius by composing the most famous of his dithyrambs, *The Cyclops*, in which he represented himself as Odysseus winning from the Cyclops the affections of his sweetheart, the nymph Galatea. This was the model for Theocritus's eleventh idyl. After leaving Syracuse, Philoxenus lived at Tarentum, and later in Greece, and died at Ephesus. He wrote 24 dithyrambs in all, which were greatly admired in antiquity. Of these only insignificant fragments remain. The poem entitled *The Banquet* (Δεῖπνον), of which much is extant, is generally ascribed to this Philoxenus; but it is probably the work of a Philoxenus of Leucas. The fragments are published by Bergk, *Poetæ Lyrici Græci*, vol. iii. (Leipzig, 1882).

PHILTER, or **PHILTRE** (Lat. *philtrum*, from Gk. φίλτρον, *philtron*, φάρμακον *pharmakon*, love charm, from φιλεῖν, *philein*, to love). An artificial means of inspiring and securing love. A belief in such charms seems to have been generally prevalent from an early age. Among the Greeks and Romans (among the latter in the later days of the Republic, and under the emperors), love charms, and especially love potions, were in continual use. Probably certain poisonous or deleterious herbs and drugs were among their chief ingredients, to which other substances, animal as well as vegetable, are said to have been added, coupled with the employment of magic rites. Thessaly was famous for producing the most potent herbs, and her people were regarded as the most skillful practicers of magic arts, whence the well-known *Thessala philtra* of Juvenal (vi. 610). These potions were violent and dangerous, producing madness and death, instead of merely serving the purpose for which they were intended. The use of philters seems to have been not unknown during the Middle Ages; and in the East, belief in the power of love potions has never died out.

PHINEAS (fĭn'ê-*as*) **FINN**, THE IRISH MEMBER. A novel by Anthony Trollope (1869). It is the first of a series of political tales, *Phineas Redux*, *The Prime Minister*, and *The Duke's Children*, in which Finn and most of the characters of the story reappear. The hero, a handsome young Irishman, goes to London and enters Parliament. Much of his success is due to the Standish family, particularly Lady Laura. At the close he throws up his political career, retires to Ireland, and marries his former sweetheart, Mary Flood-Jones.

PHINEUS, fĭn'ê-ŭs *or* fī'nūs (Lat., from Gk. Φινεύς). A blind soothsayer, the son of Agenor, and King of Salmydessus in Thrace. Because of his cruelty to his children by his first wife, when his second wife accused them falsely, he was punished with blindness and was tormented by the Harpies, who seized or defiled all the food placed before him. He was delivered from the monsters by Zetes and Calaïs, and in return directed the Argonauts in their expedition. Other traditions represent him as being slain by Heracles or by Boreas.

PHIN'TIAS (Lat., from Gk. Φιντίας). A friend of Damon. See DAMON AND PHINTIAS.

PHIPS, or **PHIPPS**, Sir WILLIAM (1651-95). The first royal Governor of Massachusetts. He was born at a border settlement, since called Woolwich, on the Kennebec River, in Maine, and was one of a family of twenty-six children, all of the same mother. Till eighteen years of age he was employed in keeping sheep, but dissatisfied with this occupation, he became a ship-carpenter, and removed to Boston. There he learned to read and write, and also married a widow with some property. Some years later he conceived the idea of fishing up treasure stored in a Spanish galleon that had been wrecked fifty years before in the West Indies. The English Admiralty fell in with this plan and gave him command of a frigate, but after a long search he returned unsuccessful. A little later he was sent out again in a vessel provided by the Duke of Albemarle and others, and this time he found a wreck and took from it treasure to the value of about £300,000. As a reward for his success, he received as his share £16,000, the honor of knighthood, and the appointment as sheriff of New England. In

1690 he was sent by Massachusetts with a fleet of eight vessels against the French settlement of Port Royal in Acadia, and succeeded in capturing it. Later in the same year he commanded a larger expedition, consisting of 34 vessels and more than 2000 men, against Quebec. So active, however, were the French under Count Frontenac that the attempt failed, and on the way back to Boston nine of the vessels were wrecked. In 1692, through the influence of Increase Mather, the agent of the colony in England, Phips was appointed Governor of Massachusetts, under the new charter. One of his first official acts was to commission a special court for the trial of those accused of witchcraft, but some months later he suspended its sittings. As Governor he displayed many of the bluff and choleric traits of a sea captain; among other things, he cudgeled Brinton, the collector of the port of Boston, and caned Captain Short of the Royal Navy. In 1694 he was summoned to England to answer complaints made against him, and while there died suddenly of a malignant fever. Phips was a man of great energy and determination, but possessed no remarkable intellectual capacity; and he appears to have been strictly honest in his private dealings, though he deemed it no sin to steal from Frenchmen. There is a curious life of him in Cotton Mather's *Magnalia* (London, 1702), but more trustworthy is that by Francis Bowen in vol. vii. of the first series of Sparks's *American Biography* (New York, 1834-37). Consult, also, Hutchinson, *History of Massachusetts*; Parkman, *Count Frontenac and New France Under Louis XIV.* (Boston, 1877); and Myrand, *Sir William Phipps devant Québec* (Quebec, 1893).

PHIZ. The pseudonym of the English caricaturist and illustrator Hablot Knight Browne (q.v.).

PHLEBITIS (Neo-Lat., from Gk. *φλέψ*, *phleps*, vein), or INFLAMMATION OF THE VEINS. Although seldom an original or *idiopathic* disease, it is a frequent sequel of wounds, in which case it is termed *traumatic* phlebitis, and is not uncommon after childbirth. (See PHLEGMASIA ALBA DOLENS.) It commonly arises by the extension of an inflammation from contiguous structures, as in phlegmonous erysipelas or cellulitis, or by the plugging up of a vein by an embolus or thrombus. If severe, the disease begins with a chill or chilly sensations, and a rise in temperature. There is great tenderness and pain along the course of the affected vessel, which feels like a hard knotted cord, and rolls under the fingers. If the vessel is small the consequences of its obstruction may be of little importance, but when a large vein is affected the consequences are always dangerous, and may be fatal.

Phlebitis may terminate in one of several ways. The most favorable is by simple resolution—the clot is absorbed, the vein becomes permeable, and circulation is reëstablished. In other cases organization of the clot takes place, little blood vessels growing into it, from the walls of the vein, and the latter finally becomes a fibrous cord. The circulating blood is diverted to other channels which gradually dilate to accommodate the increased flow. Again, the clot may become infected, if it is not so from the beginning, undergo purulent softening, and the pus either be discharged by the formation of abscesses, or emptied into the blood current to be carried by the general circulation to all parts of the body. These purulent particles find lodgment in the large viscera, such as the liver, spleen, kidneys, and give rise to multiple abscesses. In the liver this frequently happens from inflammation of the portal veins. This general distribution of septic material is known as *pyæmia* (q.v.) An organized clot may in rare instances become calcified by the deposition in it of lime salts, and form a *phlebolite*.

The treatment of phlebitis comprises rest in bed, elevation of the part, and the local application of antiphlogistics—lead water and opium at first, hot fomentations later. If abscesses form, they must be opened and drained. In certain cases it is possible to ligate the vein above and below the clot, open the vessel, and wash out the purulent material. The internal treatment varies with the symptoms, but in general must be stimulating.

PHLEB'OLITE (from Gk. *φλέψ*, *phleps*, vein + *λίθος*, *lithos*, stone). A calcareous concretion formed by the degeneration of coagulations in veins. It is not infrequently to be felt as a nodule varying in size from a pinhead to a small bean along the course of chronically inflamed veins of the lower extremity, and phleboliths have been known to attain considerable size.

PHLEBOTOMY. See BLEEDING.

PHLEGETHON, flĕg'ē-thŏn (Lat., from Gk. *φλεγέθων*, from *φλέγειν*, *phlegein*, to burn). In Greek mythology, a river of the lower world, along with Acheron, Cocytus, and Styx (qq.v.). In Homer it unites with Acheron, as does Cocytus, a branch of the Styx. Later writers described its fiery torrent and scorched and desolate shores.

PHLEGMA'SIA AL'BA DO'LENS (Neo-Lat., painful white inflammation), or MILK-LEG. A painful general swelling of a limb, due to the obstruction of the veins; a plastic phlebitis. It is due to pressure, general disease, sepsis, or thrombosis. Milk-leg occurs principally as an affection of women in childbed, occasionally during typhoid fever. The first symptom is a rise of temperature, which may be overlooked. Pain first attracts attention, felt on the inside of the thigh, in the groin, and in the calf, of a very severe character. There may be numbness, tingling, cramps, or creeping sensations. The limb swells early from a soft œdema, the skin being white and shining, often waxy. Blue veins may stand out prominently on the posterior part of the limb. Fibrinous coagula may be detached and carried along in the circulation to some other part, as the lung, forming embolism. Paralysis of motion, disorders of sensation, and wasting of the limb may occur. The treatment consists of supporting the limb on a higher level than the trunk; punctiliously avoiding any jarring of it; maintenance of the recumbent position for at least a month; fomentations to the limb, which must be wrapped, in the intervals, in cotton; support of the heart with appropriate drugs; control of pain with analgesics and of insomnia with hypnotics. The great danger is from pulmonary embolism, which is almost invariably fatal.

PHLEGRÆ'AN PLAIN (Lat. *Phlegræi Campi*). A region west of Naples, embracing the volcanic plain on the Campanian coast from

Cumæ to Capua. There legend placed the scene of the combats between the gods and the giants. The Romans filled it with palatial villas, and their poets celebrated its charm and productiveness. The volcanic disturbances to which the region has been subject have left of the magnificent buildings of the Romans only confused ruins, in part submerged under the sea.

PHLEGYAS, flĕj'i-ăs (Lat., from Gk. Φλεγύας). The son of Ares, and father of Ixion and Coronis. His daughter became by Apollo the mother of Æsculapius. Phlegyas was so incensed that he set fire to the temple of the god, and for this was condemned to everlasting fear in Tartarus, where an overhanging rock constantly threatened to fall on him.

PHLOEM, phlō'ĕm (from Gk. φλοιός, *phloios*, bark), or BAST. That portion of a vascular bundle in plants including the sieve tissue, parenchyma, and bast fibres, and in ordinary trees forming the inner bark. See STEM.

PHLOGIS'TON. See CHEMISTRY.

PHLOG'OPITE (from Gk. φλογώψ, *phlogōps*, flaming-red, from φλόξ, *phlox*, flame + ὤψ, *ōps*, face). A magnesium mica, similar to biotite, but differing from it in composition by usually containing fluorine and less iron. It crystallizes in the monoclinic system, has a pearly lustre, and is usually of a light yellow to brown and red color. The phlogopite occurs in serpentine rocks and frequently in association with limestone or dolomite. Phlogopite often exhibits asterism, especially when seen by transmitted light, as when a candle flame is viewed through a thin sheet. This property has been shown to be due to minute needle like inclusions arranged chiefly in the direction of the rays of the pressure figure, producing a distinct six rayed star. Phlogopite is found in Finland, Sweden, Switzerland, and in the United States at various localities in New York, New Jersey, and also in Canada.

PHLOX (Lat., from Gk. φλόξ, sort of flower, flame, from φλέγειν, *phlegein*, to burn; connected with Lat. *flagrare*, to burn, Skt. *bhrāj*, to shine brightly). A genus of mostly tall, erect, spreading perennial herbs belonging to the order Polemoniaceæ, natives of North America. The

CULTIVATED FORM OF MOSS PINK (*Phlox subulata*).

species, nearly all of which have a wide natural distribution within the United States, have entire leaves, and generally very showy flowers either solitary or in terminal clusters. Owing to their hardiness, easy cultivation, and the size and beauty of their flowers, many hybrid varieties with single and double flowers, in many colors, forms, markings, and long period of bloom, and a few of the pure species, are grown in gardens, being well adapted for planting on rockeries and in borders and groups. The best known annual species of this genus is *Phlox Drummondii*, a native of Texas, from which all annual phloxes now in cultivation have been derived. *Phlox pilosa* is a somewhat variable species which flowers from May to August. *Phlox reptans* is native to the Alleghany Mountains. *Phlox Stellaria* is much prized as an ornamental plant on account of its numerous white flowers. The ground or moss pink commonly grown in gardens is *Phlox subulata*. The wild sweet William (*Phlox divaricata*) has pale lilac or bluish flowers appearing in spring and early summer. All the species of phlox grow readily in ordinary rich soil; the annuals from seeds and the perennials from seeds, division of the stools, or cuttings of the stems and roots. The seeds are sown early in the spring, given gentle heat, and after the seedlings are large enough they are transplanted, hardened under glass, and later set out in the open. The stem cuttings are made in summer and placed in fine sandy soil under cold frames or in greenhouses. The root cuttings when slightly covered with soil and placed in gentle heat sprout readily. After the cuttings have rooted they may be treated like the seedlings.

PHOCÆ'A (Lat., from Gk. Φώκαια). The northernmost of the Ionian cities of Asia Minor, about twenty miles northwest of Smyrna. It was said to have been originally settled by Phocians. It was included in the Ionian confederacy, and was one of the most flourishing and powerful of the Asiatic Greek cities. Its sailors were famous for the daring with which they pushed their fifty-oared war-vessels (not the heavy merchant craft) into the western seas. The westernmost colony of the Phocians was in Mænaca, in Spain, and they were on close terms of friendship with Arganthonius, King of Tartessus. Their most famous colony, however, was Massilia (Marseilles). Unable to defend themselves against Harpagus, the general of Cyrus, they abandoned their city and sailed to Chios (c.540 B.C.). Part of them subsequently decided to return and accept the Persian rule, but the majority sailed to Corsica and settled in Alalia. Attacked by the Carthaginians and Etruscans, who resented Greek entrance upon these lands, they were victorious in a great naval battle, but thought it wiser to abandon their settlement and move to Southern Italy, where they founded Hyele, or Elea (Velia). Phocæa seems to have continued to exist, though it is scarcely mentioned till it was captured and plundered by the Romans in the war with Antiochus. New Phocæa was founded by some Genoese about 1420, and this spot is now occupied by a little village, Phokia, while the site of the old city is still called Palæo-Phokia.

PHOCAÏS, fō-kā'ĭs. An epic poem ascribed to Homer, and said to have been composed by him in Phocæa.

PHO'CAS (Lat., from Gk. Φωκᾶς, *Phōkas*) (?-610). Byzantine Emperor from 602 to 610. He was an obscure centurion in the army, which was fighting the Avars on the Danube, when in 602 the soldiers rose in rebellion against the Emperor Maurice (q.v.), and Phocas was chosen their leader. He invested Constantinople, and after the forced abdication of Maurice was chosen and crowned Emperor. His first act was to cause the

public execution of Maurice and his five sons, and throughout his reign he was notorious for his cruelty. In Europe an ignominious peace was maintained, while in Asia unsuccessful war was waged against the Persian King Khosru II. (q.v.). He gave his only child in marriage to the patrician Crispus, and the images of the couple were indiscreetly placed by some of their friends in the circus, which was a privilege of royalty only. After this Crispus no longer felt secure, and he conspired with the rebellious exarch of Africa, Heraclius, to dethrone Phocas. This was accomplished in 610, and the tyrant was tortured and beheaded.

PHOCAS, Column of. A famous column in the Roman Forum, erected in 608 by the exarch Smaragdus in honor of the Eastern Emperor Phocas, and once surmounted by a gilded statue of Phocas. The column is 54 feet in height, and is of a better style than that which prevailed at the time of its dedication. It is therefore supposed that it may have been taken from some earlier edifice, or that an already existing monument was rededicated by Smaragdus. It was covered by the accumulated rubbish of centuries till 1813, when it was unearthed by the Duchess of Devonshire.

PHOCION, fō'shī-ŏn (Lat., from Gk. *Φωκίων, Phokiōn*) (c.402-317 B.C.). An Athenian general. He was of humble origin, but received a good education and studied under Plato and Xenocrates. His first public service was performed under Chabrias at Naxos in B.C. 376. About 349 he was sent into Eubœa to quell a disturbance that had been fostered in Eretria by the partisans of Philip of Macedon, and won a victory at Tamynæ. Some years later he led a body of Athenian hoplites to Megara, crushed Philip's faction there, and reëstablished the long walls to Nisæa; and also again conducted a force to Eubœa, where he liberated Oreus and Eretria from Macedonian influence. In 340 he was sent to the Propontis to act against Philip, who, besides suffering a number of minor reverses, found himself forced to abandon the siege of Byzantium and Perinthus. In politics, however, Phocion was a supporter of Philip and an adversary of Demosthenes, though not from mercenary or traitorous motives. When, after the destruction of Thebes in 335, Alexander sent to Athens demanding the surrender of Demosthenes and the other leaders of the anti-Macedonian party, Phocion advised compliance with the King's wishes. The proposal was rejected by the people, and an embassy was sent to Alexander to deprecate his resentment, but not until a second embassy had been sent, at the head of which was Phocion, was the King induced to remit his terms. After the death of Antipater Phocion became implicated in the intrigues of Cassander, the rival of Polysperchon, and was forced to flee to Phocis, but was surrendered to the Athenians and by them condemned to drink the hemlock. His body was carried out of Attica into the Megarid and there burnt. Shortly after his death there was a revulsion of feeling in his favor among the Athenians. They then celebrated his funeral obsequies at the public expense, and erected a statue in his honor. Consult Plutarch's *Life of Phocion.*

PHO'CIS (Lat., from Gk. *Φωκίς, Phōkis*). In ancient geography, a division of Northern Greece, bordered on the west by Ozolian Locris and Doris, on the north by Epicnemidian and Opuntian Locris, on the east by Bœotia, and on the south by the Gulf of Corinth. The greater part of the country is mountainous, with Parnassus filling the central and western portion, and only a section in the northeast, through which the Bœotian Cephissus flows, is fertile. The chief town was Elatea, which commanded the entrance into Bœotia from the north. Other towns of some importance were Daulis, Abæ, the seat of an ancient oracle, and Hyampolis, but the most conspicuous place, to which the fame of the land was chiefly due, was Delphi, whose inhabitants, however, always claimed that the control of the oracle did not belong to the Phocians. The State was a league of 22 cities, most of which were of small size. The Phocians seem to have been akin to the Dorians, though there were elements derived from earlier settlers in those regions, and there is some evidence for colonization in the southern portion from Crete and the Peloponnesus. They do not play a prominent part in the earlier history of Greece, though we hear of a desperate defense against the advance of the Thessalians, and in general they appear as enemies of the Thessalians and Bœotians and friends of the Athenians, who supported their claim to control Delphi. In B.C. 357 the Amphictyonic Council, apparently through Theban influence, imposed a heavy fine on the Phocians for cultivating some land belonging to the Delphic oracle. The Phocians resisted the sentence and were favored, but not actively assisted, by Athens and Sparta, who were at that time on bad terms with the Council and hostile to Thebes. The Phocians seized Delphi and 'borrowed' the temple treasures with which to maintain their army. For ten years the war was waged with no decisive results, though in general to the advantage of the Phocians. Even the growing power of Philip of Macedon did not check them, for while he was victorious in Thessaly, he could not pass Thermopylæ, which was held by a Phocian army and an Athenian fleet. The Peace of Philocrates (B.C. 346) between Athens and Philip left the Phocians helpless, and the sentence of the Amphictyons, which expelled them from the Council, condemned them to an enormous fine and dispersed them into small villages, thus practically removing them from future history.

PHOCYLIDES, fō-sil'i-dēz (Lat., from Gk. *Φωκυλίδης, Phokylidēs*) (c.560 B.C.?). A Greek poet of Miletus, contemporary with Theognis. He wrote chiefly didactic poems in two or three verses of hexameters or elegiac metre, the eighteen extant fragments of which have been included in almost all of the collections of the lyric and gnomic poets. Ποιήμα νουθετικόν, the admonitory poem, in about two hundred and thirty hexameters, which has been preserved under his name, is now supposed to have been the work of an Alexandrine Jew of the first century B.C. Consult: Bergk, *Poeta Lyrici Graci* (5th ed., Leipzig, 1900 et seq.); and Bernay, *Ueber das phokylidäische Gedicht* (Berlin, 1856).

PHŒ'BE. (1) A name applied to the goddess Artemis or Diana (q.v.). (2) In Shakespeare's *As You Like It*, a fickle shepherdess who falls in love with the disguised Rosalind, but at last marries the shepherd Silvius, her former lover. (3) A New England girl of strong common sense in Hawthorne's *Marble Faun.*

PHŒBE-BIRD. A small olive-green, brown-headed tyrant flycatcher or pewee (q.v.) of the United States, very familiar in gardens and named in imitation of its call. It makes a cup-shaped nest of mud and moss, which it attaches to rocky ledges and cliffs, or often to the piers of bridges, eaves of houses, and the like, and lays white eggs.

PHŒBUS, fē'bŭs (Lat., from Gk. *φοῖβος, phoibos*, bright, pure). A title of Apollo, which even in Homer has become closely joined to his name. It refers to the god as the purifier from all stains of sin. Originally Phœbus seems to have been an independent deity, but the transparent meaning of the name prevented the development of a personality, and made easy the absorption in the great defender from all evil, Apollo.

PHŒBUS, William (1754-1831). A Methodist pioneer preacher. He was born in Somerset County, Md., and entered the ministry in 1783. He was a member of the Christmas Conference at Baltimore in 1784; in 1798 he located and practiced medicine in New York, but reëntered the ministry in 1806. He desired the church to be called the Evangelical Church of America, and wrote a work entitled *An Essay on the Doctrine and Order of the Evangelical Church of America as Constituted at Baltimore, 1784* (1817). He edited the *Experienced Christian's Magazine* (1796). His grandson, George A. Phœbus (1830-1903), entered the Philadelphia Conference, 1853, and afterwards became a member of the Wilmington Conference. He published *Beams of Light on Early Methodism in America, Chiefly Drawn from the Papers of Rev. Ezekiel Cooper* (1887), a work of very great importance as a source book of Methodist history.

PHŒNICIA, fē-nish'i-ȧ (Lat., from Gk. *Φοινίκη, Phoinikē*, Phœnicia). The name used by the Greeks and Romans to designate the strip of territory about 200 miles long, from 5 to 15 miles broad, along the Mediterranean coast of Syria. On the east this tract is bounded by the Lebanon Mountains, being watered by the streams that flow from them. The northern and southern limits are not easily defined and varied from time to time. Ptolemy fixes the northern boundary at the Eleutheros (Nahr el-Kebir) and the southern at Mount Carmel, but there were undoubtedly Phœnician settlements both farther north and farther south. The origin of the name is unknown. Its derivation from *phoinix* (date palm) is uncertain, as there is no evidence to show that that tree grew in Phœnicia. A more probable derivation is from the Greek *phoinos* (blood-red), referring to the purple which the Phœnicians introduced into Greece. In the Old Testament this territory is designated as part of Canaan (q.v.), and the inhabitants as Sidonians. This latter designation occurs also in Homer, and points to a period when the land was under the leadership of the City of Sidon. Being shut off from the east and the south by mountain ranges, and on the west limited by the sea, it was impossible for Phœnicia to play any important political rôle. Nor were the different settlements ever welded together into one powerful kingdom. They formed a nation with one or the other holding the hegemony. The northernmost port was Arvad or Aradus (the modern Ruad, mentioned in Ezek. xxvii. 8, 11, and in Assyrian inscriptions, situated on an island near Tripolis. A second port was Simyra (Assyrian, Sumari or Simirra), mentioned in the Amarna letters (c.1400 B.C.), and in Gen. x. 18. The most important of the northern towns was Gebal, called by the Greeks Byblos (q.v.). It had relations with Egypt and Assyria in very early times and exercised a sort of supremacy over the country around it, rivaling Sidon and Tyre in the south and preserving its independence through the greater period of Phœnician history. The city of Berytus (Beirut) belonged originally to the Principality of Byblos, but afterwards became independent. Farther south were the cities of Sidon, Sarepta, Tyre, and Acco (Acre), all of which were old settlements, going back at least to about B. C. 1800, when Egypt inaugurated her Western Asiatic campaigns. Several of these cities stood on islands and were thus fortified by nature. Of these cities Tyre and Sidon (qq.v.) arose to a controlling position and from time to time interchanged as the ruling power. There were also a number of inland towns, such as Kana, but they never attained to any importance.

It is impossible to say at how early a date the Semitic population formed settlements here. They must have come upon one of the migratory waves that issued from the Tigris-Euphrates valley, and their close relationship to the Hebrews shows that they branched off with them from the Aramæan wave which formed permanent settlemens in Northern Syria. At the time the Amarna tablets were written (c1400 B.C.) the coast towns were all occupied by Semites; and from what is now known of the history of the relations between Babylonia and Syria in early days, the settlement of the Semites in Phœnicia may be placed c.2500 B.C. or earlier. This would agree with the assertion of Herodotus that Tyre was founded about B.C. 2730.

What little is known of the history of Phœnicia may be divided into six periods: (1) From the earliest time to the Egyptian supremacy, c.1800 B.C.; (2) the period of Egyptian control to c. 1400 B.C.; (3) the advance of the Hittites and the Assyrians to c.1100 B.C.; (4) the period of independent development, B.C. 1100 to 900; (5) Assyrian and Babylonian control, to the downfall of the Neo-Babylonian dynasty, B.C. 539; (6) the period of the Persian, Greek, and Roman supremacy. The earliest period must have been dominated by Babylonian influences, as we find Babylonian script and language used as the medium of diplomatic correspondence. This was maintained even after the rulers in the Phœnician and Palestinian cities had become vassals of Egypt. The Babylonian King Sargon (B.C. 3800) extended his conquests as far as Cyprus, and he must have laid a part of Phœnicia under tribute. Each settlement at the time formed a sort of independent principality. In the papyrus Anastasi I. (sixteenth century B.C.) the Phœnician cities Byblos, Berytus, Sidon, Sarepta, Tyre, and Aradus are mentioned. The influence of Egypt was strong. She exacted a tribute, kept the principalities under native rulers, and discouraged any coalition. The country unfortunately lay between Egypt and her great rival, the State of the Hittites. This people, having secured possession of the districts around Damascus and Tunip, maintained a successful opposition to the Egyptian armies; and Rameses II. was obliged to make a treaty with them, yielding the

territory north of Mount Carmel. The city of Tyre was at this time gradually reaching the position of eminence which it kept for several centuries; Sidon played a secondary part, the oldest colonies having been sent out by the former city. In the thirteenth century Assyria first commenced to check the growing power of the Hittites. For a time the coast cities were forced into a position of vassalage; but after the death of Tiglathpileser I. (c.1100 B.C.) Syria, Palestine, and Phœnicia enjoyed a brief respite. In Phœnicia a coalition was formed with Sidon at its head. Tyre, however, set aside her rival and under Abibal (tenth century B.C.) and his son, Hiram, extended her control to Cyprus. It was this Hiram who furnished workmen and material for Solomon's building operations in Jerusalem. (See HIRAM.) Asshurnasirpal (B.C. 870) received tribute from Tyre, Sidon, Byblos, and other cities. Assyria had great difficulty in holding these distant places. Rammannirari III. had again to subdue Tyre and Sidon (B.C. 803), and Tiglathpileser III. (B.C. 734 to 728) not only sent one of his generals there, but colonized people of other nations in the district. King Luli (Elulæus) fell off completely from Assyria, and, under the leadership of Hezekiah of Judah, made common cause with Tirhaka. Sennacherib (B.C. 700) forced him to flee to Cyprus, putting a new king, Ittobaal, in Sidon. In B.C. 678 Sidon was destroyed and the various rulers in Phœnicia and Cyprus did homage to the Assyrian King. The power of Assyria was, however, on the wane, and under Psammetik I. (B.C. 625) Egypt commenced to exert her sway once more over the coast. In B.C. 585 Tyre was again invested by Nebuchadnezzar II., and though the other Phœnician cities fell early into his power, it held out for 13 years. King Ittobaal and his family were carried off to Babylon. In B.C. 539 Phœnicia, after the rule of a few legitimate kings, sent there from Babylon, became part of the Persian kingdom.

During the Persian period Sidon forged ahead of her old rival. The seacoast towns, with their large fleets, were necessary for the maritime operations of the Persian kings. Three hundred Phœnician triremes warred with Xerxes against Greece. Eighty Phœnician ships engaged in the battle of Cnidus (B.C. 396). Like its old rival, Sidon became involved in the quarrel of the two great nations who fought for the supremacy of Western Asia. Under Tennes II. it joined with Nectanebo II. of Egypt and might have been successful had not its King betrayed it to Artaxerxes III. This caused a great catastrophe (B.C. 345) in which 40,000 lost their lives. The power of Sidon was broken. On the reappearance of Alexander the Great in Phœnicia, Sidon, Aradus, and Byblos immediately submitted, but Tyre held aloof and capitulated only after a siege of seven months (July, B.C. 332). Eight thousand lost their lives, 30,000 were sold as slaves. Sidon and Tyre, and together with them Phœnicia, vanished from the world's history. Yet we hear of the cities again during the reign of the Ptolemies, and a certain amount of autonomy must have been given at least to Sidon and Tyre. Phœnician inscriptions tell of independent rulers in the fourth and third centuries B.C., notably in Sidon, where the family of Eshmunazar ruled. In B.C. 197 Phœnicia came into the power of the Seleucid kings of Syria and became involved in the collapse of that kingdom. In B.C. 64 it became with Syria a Roman province; and although the trade of the seacoast towns was greatly benefited thereby, their Phœnician character was rapidly lost and forgotten.

The influence of Phœnicia was, however, not confined to the narrow coast strip of Syria. At an early date her merchants brought about a contact between the East and the West, which constituted an important factor in ancient history. These merchants traveling through the Mediterranean formed colonies wherever they went and many of the place-names along the African coast seem to show that Phœnicians became there the dominant factors.

Only some of the general features of Phœnician religion are known. Each town had its protecting deity, with whom a female consort was often associated. In many cases this god was known simply as the Baal, i.e. Lord, of the place. In others he bore a special name, such as Melkart in Tyre, Sakkun in Carthage. The Phœnician pantheon was quite large, though some of the names may be different designations applying to one deity. The most important of their deities were Adonai (Greek Adonis, q.v.), worshiped in Byblos and whose cult was also transferred to Cyprus; Eshmun, a sun god, worshiped at Sidon, Berytus, and Carthage, and in Cyprus; Melkart, at Tyre; Tanith, the great goddess of Carthage, who was often associated with a Baal, as was Astarte on the Phœnician mainland. Foreign gods were also easily admitted into this pantheon; e.g. the Syrian gods Reshef and Anat; the Egyptian Isis, Osiris, Bast, and Horus; and the Babylonian Hadad. A parallel to this is found in the general tendency of the Phœnicians to adopt the art, culture, and myths of the surrounding peoples. Their religion therefore presents a strangely conglomerate character. Traces of primitive conceptions which they shared with other Semitic peoples persisted to the latest period. Trees, stones, and rivers were regarded as sacred principles underlying the animistic stage of religious development. In early days the cult was carried on in groves or on the tops of mountains. In later times small sanctuaries were erected and inclosed in a sacred area. Subsequently, and perhaps under foreign influence, more elaborate structures were erected, temples with a large altar in a court open to the sky to which was attached a covered shrine, which was regarded as the holy of holies. The chief festival of the Phœnicians seems to have been the one which was celebrated at the time of the summer solstice, commemorating the death and return of Adonis. The priesthood must have assumed large proportions, but it does not seem to have wielded the power that the priesthood did in Egypt and Babylonia, though the ruler at times was also chief priest.

BIBLIOGRAPHY. (Leipzig, 1901).

PHŒNICIAN ART. The art of the Phœnicians was both cosmopolitan and commercial.

Their lack of originality and of artistic sense made it easy for them to turn their energies to copying the arts of their powerful neighbors, especially Egypt and Assyria, and to cultivating those branches of art that were merchantable and transportable. They show the influence of the Hittite and other Syrian tribes in their magnificent fortifications, and of the Iranians, perhaps, in their lack of monumental temples. A branch of their school in Cyprus developed monumental sculpture in stone under archaic Greek influence, and this was echoed in the Phœnician settlements in Spain (e.g. Elche); but otherwise large sculptures in stone seem rare. It was otherwise with works in metal, from bronze to gold, and in terra-cotta, glass, iron, and textile objects. In all these branches the Phœnician artisan distinguished himself, and supplied most civilized nations. It was after B.C. 1000 and before 500, when international commerce was almost exclusively in the hands of the Phœnicians, that this art was most brilliant and that we find its products in the tombs, palaces, and sanctuaries of nearly every country of the Mediterranean and of Western Asia. Later the African branch, with its centre at Carthage, continued its history, even under Roman dominion, as is being brilliantly shown by Delattre's excavations.

Architecture. The eclecticism of the Phœnicians appears in their monuments. From the few surviving remains it would seem that Babylonian, Egyptian, Assyrian, and Persian influences alternated. The little temple of Amrith is thoroughly Egyptian, and so are the less important tabernacles at Ain-el Hayat. The general scheme of the larger temples was a court in which the cella or tabernacle rose on a basement: a plan comparable to that of the Temple of Jerusalem. The temples of Cyprus should be reckoned with those of Phœnicia, though they approach closer to the Greek type with columnar portico. Of the famous temples of Tyre, Sidon, Gebal, and Paphos nothing remains. Almost as thorough a destruction has overtaken the military and civil constructions by which the Phœnician cities were made almost impregnable. Something remains at Aryad, Berytus, Sidon, and at Eryx, in Sicily, in magnificent masonry that passes from the earlier polygonal and cyclopean to the later Hellenic course construction in stone. Thapsus alone has preserved part of its harbor constructions—so important in all Phœnician cities. As in the case of the Etruscans, we can learn something from the sepulchral architecture, both the free-standing specimens, like the circular monolith of Amrith with its guardian lions, and the other one at the same place in the form of a house with pyramidal roof, and the other type of rock-cut chambers, such as those of Carthage and nearly all the cities.

Sculpture and Minor Arts. The anthropoid sarcophagi, of which the Louvre possesses a number, while others, found at Sidon, are now in the Museum of Constantinople, show the influence of Egypt on monumental Phœnician sculpture. But the sarcophagi and statues found by Cesnola and others in Cyprus are by far the largest part of the Phœnician plastic patrimony. Here, even more than in Persian sculpture, we find that the Hellenic idea of letting the form of the body pierce through the drapery was adopted, and that the attempt at expressiveness took the form of the grimace or smile. There is a curious amalgamation in this school of such Hellenic elements with others from Egypt and Assyria, with the composition varying according to political predominance. Statues of gods and goddesses as well as of priests, sometimes colossal, show facility of execution. The sarcophagi, especially that from Amathus, are of equal importance, and are in high relief, in contrast to the Assyrian low-relief technique.

In the field of metal work the most extraordinary objects that have been preserved are the great bronze votive shields from the cave of Zeus on Mount Ida, in Crete, with their Egyptian sphinxes, Assyrian lions, and figures of Merodach and zones of animals like those on the early Greek vases (especially Corinthian). Equally important on a smaller scale are the silver dishes or pateræ found in Assyrian palaces (Nimrud), in Cyprus, and in some Italian tombs, with their exquisite scenes engraved or in relief, from mythology, legend, or daily life. The Dali cup in the Louvre, the Palestrina patera and those from Curium in the Metropolitan Museum, are the finest pieces of work preserved from Oriental antiquity. The mixture of subjects shows that the Phœnician artist cared less for the significance than for the artistic quality of the design, and often made mistakes in copying scenes originally conceived by Assyrian or Egyptian artists.

The gold and silver ware on the tables of Oriental monarchs, their bronze serving-vessels, were usually the work of these Phœnician artists, who were everywhere, even in Nineveh. It was not quite the same with ivories, only some of which are Phœnician. But, on the other hand, the Phœnicians absorbed nearly all the trade in glass vessels, after learning the art from Egypt, and the glass factories of Tyre and Sidon and Berytus remained famous even through the Middle Ages. The collection in the Metropolitan Museum, mostly from the Charvet collection, one of the finest in existence, contains many Phœnician pieces, and the tombs that are continually being opened in Phœnicia furnish more glass than any other class of objects.

It would seem as if in jewelry the Phœnicians played the important rôle of giving models to Greek and Etruscan artists after learning from Egyptian and Asiatic artists. Lotus flowers and anthemions, heads of Isis, of Hathor, and other gods and genii, animals and birds in relief or as pendants, rosettes and groups of balls hanging from chains, formed most elaborate designs in earrings, necklaces, tiaras, etc. In the field of engraved stones, precious or rare, the Phœnicians imitated as usual; the Egyptian scarab and the Assyro-Babylonian cylinder and seal were equally popular, with borrowed mythological scenes, until, in the fourth century B.C., the fashion turned exclusively to Greek models.

Bibliography. The standard work of reference is the two volumes on Phœnicia in Perrot and Chipiez, *History of Ancient Art*, but this can be supplemented for architecture by Renan, *Mission de Phénicie* (Paris, 1865-74); by Fröhner, *La verrerie antique*, for the Charvet collection of glass; by Ménant, *La glyptique orientale*, for engraved gems and stones; by Clermont-Ganneau, *L'imagerie phénicienne* (Paris, 1880), for the silver pateræ; by Orsie Halbherr, *L'antro di Zeus in Creta* (Rome, 1883), for the Phœnician shields, etc.

PHŒNICIAN LANGUAGE. The language spoken by the inhabitants of Phœnicia. It belonged to the Hebræo-Phœnician division of the Semitic family of languages, and represents in general an archaic stage of Hebrew and Moabitic, although it differs from the North Semitic group in certain particulars, such as having *kān* (like the Arabic *kāna*) for the copula instead of *hāyā*, as in Hebrew. Phœnician spread widely from its home as Punic colonies were founded in the islands of the Mediterranean and Ægean, in Southern and Western Asia Minor, Southern France, and especially in Northern Africa. The diffusion gave rise to variations both of dialect and script, which were, however, comparatively slight. The sources of our knowledge are the inscriptions, coins, and seals, the transliteration of Phœnician phrases in Plautus's comedy of the *Pœnulus*, and the proper names and words found in the Old Testament, in the inscriptions of Assyria and Egypt, and in classical writers. The inscriptions are by far the most important source. Although they are very numerous, the vocabulary is relatively scanty on account of their monotonous content. They cover the period from about B.C. 600 to A.D. 200. The longest are the inscriptions found at Sidon in 1855 of twenty-two lines, at Marseilles in 1845 of twenty-one lines, and at Larnaka in 1879 of twenty-nine lines. The passage in the *Pœnulus* and the words and names in other foreign sources are of value in fixing the vocalization and pronunciation of Phœnician, since the alphabet, like all the Semitic scripts, excepting the Assyro-Babylonian and Ethiopic, writes only the consonants. The alphabet, which itself seems derived from the South Arabian script, is of importance as the ancestor of the Græco-Roman family of alphabets. (See Plate of ALPHABETS.) Phœnician literature seems to have been very scanty, consisting chiefly of annals, and at least one work, by Mago, on agriculture, and has been entirely lost with the exception of Greek translations of the voyage of Hanno (q.v.) and fragments asserted to be translations of the histories of Sanchuniathon (q.v.). Consult: Schröder, *Die phönizische Sprache* (Halle, 1869); Bloch, *Phönizisches Glossar* (Berlin, 1891); Gesenius, *Scripturæ Linguæque Phœniciæ Monumenta Quotquot Supersunt Edita et Inedita* (3 vols., Leipzig, 1837); *Corpus Inscriptionum Semiticarum* (Paris, 1881–87). See SEMITIC LANGUAGES.

PHŒNIS'SÆ (Lat., from Gk. *Φοίνισσαι, Phoinissai*, Phœnician Women). A play by Euripides, so called from its chorus of Phœnician captives at Thebes. The myth which forms the subject of the play is the same on which the *Seven Against Thebes* is based.

PHŒ'NIX (Lat., from Gk. *φοίνιξ, phoinix*). The name of a mythical Egyptian bird frequently mentioned by classical writers. Herodotus (ii. 73), who says he heard the story at Heliopolis and saw a picture of the bird there, relates that the phœnix, on the death of his father, embalms the body in an egg made of myrrh and conveys it from Arabia to the Temple of the Sun at Heliopolis. According to Pliny (Nat. Hist., x. 2), there is only one phœnix at a time, and when he perceives that his end is near, he builds in Arabia a nest of twigs of cassia and frankincense and dies upon it. From the body is generated a worm which develops into the new phœnix. The young bird then conveys his father's body to Heliopolis and burns it upon the altar there (Tacitus, *Ann.*, vi. 28). According to Horapollo (ii. 57) the phœnix casts himself upon the ground and receives a wound, from the ichor of which springs his successor. But the most familiar version of the birth and death of the phœnix is that in which the bird burns itself upon a nest or pyre of odoriferous woods, and the young phœnix springs from the ashes. The interval between the bird's appearances at Heliopolis is variously stated; the period usually named is 500 years, but 1461 and 7006 years are also given. According to Tacitus (*Ann.*, vi. 28) the phœnix appeared four times in Egypt: (1) under Sesostris (q.v.); (2) under Amasis; (3) under Ptolemy III.; and (4) in the year B.C. 34.

In Greek and Roman art it was common to represent the phœnix as an eagle; but by the Egyptians, who called it *Bennu*, the bird was depicted as a heron with two long feathers growing from the back of its head and sometimes with a tuft hanging from its breast. It symbolized the morning sun rising out of the glow of dawn, and hence it was looked upon as the sacred bird of the sun-god Rē. It also represented the new sun of to-day springing from the body of the old sun of yesterday, which had entered the lower world and become one with Osiris. Hence the phœnix or *bennu* was regarded as a manifestation of Osiris and became a symbol of the resurrection, continuing to serve as such even in early Christian times. It has been supposed by some scholars that the phœnix is mentioned in Job xxix. 18 and Psalm ciii. 5, but the identification is very doubtful. Consult: Kirchmayer, "On the Phœnix," in *Collectanea Adamantaa*, No. xv., vol. ii. (Edinburgh, 1886); Wiedemann, *Religion of the Ancient Egyptians* (New York, 1897).

PHŒNIX. A city in Lee County, Ala., on the Chattahoochee River, opposite Columbus, Ga., and on the Central of Georgia Railroad (Map: Alabama, D 3). It is a residential place, and is also of considerable importance as a commercial centre. Among the chief buildings are the city hall and the fraternal society hall. Settled about 1860, Phœnix was first incorporated in 1883. It is governed under a charter of 1894, which provides for a mayor, elected every two years, and a council. Population, in 1890, 3700; in 1900, 4163.

PHŒNIX. A city, the county-seat of Maricopa County, Ariz., and capital of the Territory, 100 miles northwest of Tucson; on the Maricopa and Phœnix and the Santa Fé, Prescott and Phœnix railroads (Map: Arizona, B 3). Among the more prominent points of interest are the Capitol building, insane asylum, agricultural experiment station, city hall, court house, and high school and central school buildings. The city is a popular winter resort. It has extensive commercial interests, controlling an important trade in live stock, grain, hay, honey, wines, oranges, and other fruits. Settled in 1870–75 Phœnix was incorporated in 1881. The government, under a charter revised last in 1893, is vested in a mayor, who holds office for two years, and a council which exercises some powers of confirmation and election in administrative offices, though the majority are filled by popular election. Population, in 1890, 3152; in 1900, 5544.

PHŒNIX PARK. A public park of 2000 acres in Dublin, containing a granite monument in honor of Wellington. The park became famous through the assassination within its borders, on May 6, 1882, of Lord Frederick Cavendish, Chief Secretary for Ireland, and Thomas Burke, the Under Secretary.

PHŒ'NIXVILLE. A borough in Chester County, Pa., 28 miles northwest of Philadelphia; at the junction of French Creek with the Schuylkill River, and on the Pennsylvania and the Philadelphia and Reading railroads (Map: Pennsylvania, F 3). It has a public library and a hospital; and is an important manufacturing centre, well known for its great iron mills, boiler works, silk mills, underwear and hosiery mills. There is also a match factory. The government is vested in a burgess, chosen triennially, and a council which elects all municipal officials excepting the school directors, who are independently chosen by popular vote. The borough owns and operates the water-works. Phœnixville was settled in 1792 and was incorporated as a borough in 1849. Population, in 1890, 8514; in 1900, 9196.

PHOLAS (Neo-Lat., from Gk. *φωλάς*, a lurking mollusk which makes holes in stones). A genus of bivalve mollusks having much roughened, file-like shells with which they excavate cavities in soft rocks, in other shells, etc., for their own occupancy. See DATE-SHELL.

PHO'LUS. A centaur, son of Silenus, by whom Hercules was entertained on his journey in quest of the Erymanthian Boar. When the other centaurs were attracted to the cave of Pholus by the odor of the wine with which he regaled the hero, Hercules scattered and pursued them, but on his return found Pholus accidentally killed by one of the arrows which he had withdrawn from the body of a slain centaur, and which had dropped from his hand and stuck in his foot.

PHONAUTOGRAPH. See PHONOGRAPH.

PHONETIC LAW (Gk. *φωνητικός, phōnētikos*, relating to sound, from *φωνή, phōnē*, sound, voice; connected with *φῆναι, phēnai*, Lat. *fari*, to speak, OHG. *ban*, Ger. *Bann*, AS. *bann*, Eng. *ban*). In comparative linguistics, a formula which sums up a certain phonetic correspondence or a certain number of such correspondences. The term law in this sense is, therefore, essentially different from its application in mathematics or chemistry, and approaches rather the usage of the word as it is employed in psychology. A given phonetic law, moreover, is required to be operative only under given conditions in a given dialect or dialect group during a given period. As an example of such a law we may take the representation of the Indo-Germanic *ā* which becomes in Germanic *ō*, which remains unchanged in Gothic, Icelandic, Old Saxon, and Anglo-Saxon; as Sanskrit *bhrātar*, Greek *φράτηρ*, Latin *frāter*, 'brother,' but Gothic *brōþar*, Icelandic *brōþer*, Old Saxon *brōthar*, Anglo-Saxon *brōþor*. Further, it is a phonetic law in Old High German that such an *ō* becomes *uo*, which is changed in New High German to *ū*, so that we find corresponding to Gothic *brōþar*, Old High German *bruodar*, New High German *Bruder*. On the other hand, Indo-Germanic *ā* becomes *a* in Old Church Slavic and *ō* (written *o*) in Lithuanian, as Sanskrit *bhrātar*, 'brother,' Old Church Slavic *bratŭ*, Lithuanian *brõlis*. As the science of comparative linguistics developed, it was found that sound-changes followed certain rules. The very earliest investigators, however, seem to have paid little attention to the problem whose enunciation and discussion was destined to mark an epoch in the history of the science, the question as to the invariability of phonetic law. Yet even then it was realized that etymology (q.v.) without strict adherence to phonetic law was capricious and unscientific. The existence of such law was emphasized by the famous discovery known as Grimm's law (q.v.), which was in its turn supplemented and accentuated anew by the enunciation of Grassmann's law (q.v.), Verner's law (q.v.), and the palatal law, which postulated the existence of *e* in Pre-Indo-Germanic. In 1876 the logical result of phonetic investigations up to that time was given by Leskien, when he stated the theorem that phonetic laws know no exceptions. This was the keynote of the neo-grammarian movement. (See PHILOLOGY.) Osthoff and Brugmann two years later stated the principle in its definite form as follows: "All sound-change, in so far as it operates mechanically, is carried out according to invariable laws." By this modification of Leskien's statement the necessary scope was given for analogy (q.v.) in controverting the action of the laws. Exceptions were, therefore, only apparent, not real, and they were to be explained either by the operation of analogy or as the results of laws yet undiscovered. This latter point had already been emphasized by Leskien, as Whitney had laid stress on the importance of analogy in explanation of many difficult linguistic phenomena. The point at issue was unfortunately shifted, and the gulf between the old and new schools of grammarians widened almost hopelessly. The contention became not the nature of phonetic law, wherein all might, it would seem, be in harmony, but whether the laws were invariable or not, a problem which is yet unsolved. Without going into the details of the long discussions which followed after 1878, where Georg Curtius and Brugmann were the protagonists for the old and new schools respectively, it may be said that the net result has been a distinct gain for the neo-grammarian movement. Phonological and etymological investigation at present tacitly accepts the invariability of phonetic law. At the same time, it is not as rigidly bound by dogmatic adherence to this principle as was the case when the enthusiasm of its novelty was potent. The influence of the doctrine has, then, been most beneficial in enforcing accuracy in the application of the laws, and compelling exact and full explanation of any deviation, however slight, from their normal action. On the other hand, sufficient attention has not yet been devoted to the explanation of the laws themselves. Why, for instance, to revert to the example already given, does Indo-Germanic *ā* become *ō* in certain languages, *a* in others, and in others still remain unchanged? Phonetic changes, instead of being absolutely invariable, are only relatively uniform and obey only general tendencies. These tendencies are governed to a large extent by physiological requirements, and further by psychological processes, especially the associative faculties of analogy, imitation, and the like. Initially the changes are individualistic. If the phonetic change in question is physiologically possible and pleasing to a speech-community, however small, it may be adopted imitatively, and may then be extended analogi-

cally, and being accepted by a widening range of speakers, it may develop into a general tendency, become relatively uniform, and thus be made a phonetic law. These conclusions are confirmed by the study of living, spoken dialects, where the artificial uniformity of script does not mislead the investigator, as is too often the case with languages which have been preserved only in literary forms.

Consult: Curtius, *Zur Kritik der neuesten Sprachforschung* (Leipzig, 1885); Brugmann, *Zum heutigen Stand der Sprachwissenschaft* (ib., 1885); Schuchardt, *Über die Lautgesetze* (Berlin, 1885); Delbrück, *Einleitung in das Sprachstudium* (3d ed., Leipzig, 1893); Paul, *Prinzipien der Sprachgeschichte* (3d ed., Halle, 1898); Oertel, *Lectures on the Study of Language* (New York, 1901). See GRASSMANN'S LAW; GRIMM'S LAW; PHILOLOGY; PHONETICS; VERNER'S LAW.

PHONETICS. In its broadest sense, a study of the whole range of sounds, articulate, musical, and otherwise. It is, however, usually confined to the articulate sounds of human speech. Even in this restricted sense, it is still broad enough to include the subject of the purely acoustic or mechanical side and the anthropological or philological side. It may discuss simply the vibrations that cause any particular sensation on the human ear, or it may include an investigation of the manner and causes of the change of one articulate sound in one language at one time, into another sound in another language or at another epoch. In the first case it should consider the mechanism and methods by which the sounds are produced, and also the way in which they are made effective in the ear, and impress the brain.

The question of the variations of articulate sounds and of the symbols which from time to time may be used to represent them belongs to the sphere of comparative philology (q.v.), and is not, therefore, discussed in this article.

Confining the attention to the physics of phonetics, the subject naturally falls under three heads, or questions: What is tone quality, or the mechanical difference between two sounds? How are sounds produced in the human voice? and How are they perceived in the ear? The divisions may best be treated in the order given.

One sound differs from another in three factors, pitch, intensity, and quality. (See ACOUSTICS.) The pitch and intensity, or loudness, are of but little importance in this connection. The controlling factor is the quality. In articulation the sounds are divided into two broad classes: the vowel sounds, or those which are maintained in more or less uniform quality for an appreciable length of time; and the consonants, or those sounds which are more essentially a peculiar stopping or starting of a vowel sound, and which are apt to form the transition from one vowel to another, by some one of an infinite variety of ways.

Taking up the discussion of the vowel sounds first as being the simpler case, it is evident that these sounds, which last with a uniform character for an appreciable fraction of a second, or at least may be so prolonged, must depend for their distinguishing peculiarities upon the same factors as any other sound. As the pitch of a sound depends upon the length of the wave, and the intensity upon the height of the wave, so does the quality of the sound depend upon the shape of the wave. It has been demonstrated that any wave motion, no matter how complex, may be considered as made up of a series of simple waves of differing lengths and heights. Therefore, any quality of sound, no matter how complex, is made up of simple components, differing in pitch and intensity. By a simple sound is meant one in which the vibrating particles move in a simple harmonic motion, similar, for example, to that executed by a clock pendulum. When a violinist plays a particular note, it differs from the same note on the organ or the piano or the wind instruments only in the relative number, intensity, and pitch of the 'partials' or 'overtones' which accompany the fundamental, or 'pitch-tone.' In a manner entirely analogous the maintained sounds of the human voice differ one from another, when the same fundamental tone is being produced, only in the relative number, pitch, and intensity of the accompanying partials. It is believed by some that the 'phase-relation' of the components also affects the quality of the sound, but this is still an open question and certainly does not affect the case of articulation.

The question, then, is to determine just what are the particular combinations of elements which form the various vowel sounds. In the first place, it has been shown conclusively that the same relative components will not produce the same vowel sounds on different pitches. For example, a certain combination, bearing a definite relation to a fundamental of 256 vibrations per second, will produce a certain vowel quality, but if the rates of all these components are raised by the same interval of a fifth, the vowel quality will be quite different. In other words, that combination which is recognized as giving a perfectly satisfactory *a*, as in *father*, on a pitch of middle *c*, is entirely different from that which is similarly recognized on a pitch an octave higher.

There are two conceptions at present as to what constitutes the essential characteristic of a particular vowel sound. Some hold that each vowel sound always contains in its complex a certain characteristic tone component of definite pitch, and that the presence of this element makes that vowel. For example, *a*, as in *father*, has its essential vowel tone, and *e*, as in *meet*, would have a different tone. This theory holds that the pitch of the characteristic elements is constant, irrespective of the pitch of the fundamental, or main tone. Others believe that there is no difference in the question of tone quality in vowels from the same question as applied to any tone. Under this conception there would be no one essential component, but all would be essential and the total would be characteristic. This would mean that the difference between *o* and *a* pronounced on treble *c* is of exactly the same character as that between the two sounds when that note is played upon a flute and upon a violin. In other words, vowel quality is no different from tone quality.

The actual solution of this question is enormously complicated by the fact that habit allows the greatest possible variation in what may still be called a particular vowel. For example, the *a* in different individuals may differ more radically than the *a* and *o* in the same individual.

Helmholtz seems to hold to both theories, and gives the following as the pitches of the characteristic tones of the vowels: U = 175; O =

466; A = 932; Ā = 1568; Ėm = 1976; I = 2349. In like manner he gives the composition of those vowel sounds as made up of a characteristic combination of overtones, as follows:

VOWEL	1	2	3	4	5	6	7	8
I	*f*	*pp*	*pp*	.....	.....	.....	.....	.....
O	*mf*	*p*	*p*	*f*	*p*	.....	.....	.....
A (as o in not)	*p*	*p*	*p*	*p*	*ff*	*ff*	*ff*	*ff*
Ā	*p*	*pp*	*p*	*f*	*f*	.....	.....	.....
E	*p*	*pp*	*f*	*p*	*p*	*p*	*p*	*p*

The letters *p*, *pp*, *f*, *ff*, and *mf* have the usual musical significance.

Nevertheless the greatest difference of opinion exists as to the exact pitch of the characteristic tone, and also as to the particular combination of partials which form the particular vowel sounds. In general it seems well established that in the sound of *a*, as in *father*, the complex consists of the fundamental and the first eight or ten overtones with intensities decreasing as they rise in pitch. E, as in *meet*, has not the higher overtones, and is characterized by a relative strengthening of the third and fourth in the series. O, as in *moat*, has number four rather strong; and finally U, as *oo* in *boot*, is little if anything besides the fundamental and a little of the first overtone. It is to be understood that these overtones are in the series present in a string, or an open pipe, i.e. the rates of vibration of the fundamental and overtones are in the ratio of 1 to 2, 3, 4, 5, etc.

The question of the exact composition of any vowel on any pitch cannot be definitely and finally determined, for the simple reason that the character of the sound differs with every individual, and no one can be said to be right and all the others incorrect. General conclusions can be stated or specific analyses in particular cases.

As to the quality of the sounds in the pronunciation of the consonants little can be said at present, as the case is much more complex than that of the vowels. On the one hand, the quality is rapidly changing from instant to instant, thus offering new and especial difficulties to the analyst; and on the other hand, the simple more or less musical tones are often accompanied by a number of irregular noises like the hiss, the aspirate, etc. There are also the peculiar methods of stopping and starting the sounds, as in *p*, *b*, *d*, *g*, etc., in initials or finals. A class exists where a neutral sound is produced in the larynx, and formed into *m*, or *n*, or *th*, etc., according to the way in which the air is permitted to escape, by the nose or mouth.

Thus far no rigid analysis of the consonants has been possible, although the individual variations may be less than in the vowels.

The second branch of the subject is the apparatus and method of production of human articulate sounds. This function is performed by the joint action of the lungs, larynx, mouth, and nose. The lungs are simply the wind box, and serve to supply the air to actuate the vocal cords and produce the various sounds; they supply the raw material, and are the source of energy.

In the larynx (q.v.) is to be found the original source of all the sustained sounds that bear any resemblance to musical tones. Whisperings, hisses, aspirates, etc., are formed independent of the larynx. In the larynx is to be found a pair of cords or membranes, which may be so drawn together over the top of the windpipe that they practically close it. If air from the lungs is forced against the cords under the above conditions, they are set into vibration and produce a sound. The pitch of this sound is regulated by the length, weight, and tension of these cords, there being present in the larynx sets of muscles for the involuntary control of these three factors which determine the pitch of a vibrating cord. Confining the attention again to the vowel sounds, it may be said that the function of the larynx is to produce a sound which can be molded into any one of the vowels, and that its action is not determinative as to which vowel shall be produced. Articulation is not performed by the larynx, but by the agencies between it and the outer air. The particular variation of tone that is produced by an individual depends upon the cavities of the mouth and nose, the position of the various movable parts, as the tongue and palate, and the size and shape of the opening at the teeth or lips. In the flute and clarinet it is the number and location of the openings which determine the pitch to a large extent, but in the human voice it is the larynx which determines the pitch of the fundamental, and the size, shape, and openings of the cavities of the mouth and nose determine the quality of the sound, i.e. the vowel sound produced. Resonance as applied to this subject means that property of a mass of air by virtue of which it can pick up and intensify the vibrations which fall upon it when those vibrations are of a frequency bearing the proper relation to the size, shape, and opening of the air mass. The vocal cords produce a complex sound composed of a fundamental and a more or less complicated series of over tones; this sound passing out through the cavities of the mouth and nose has certain tones reënforced by virtue of the resonance of the cavities, while other components are practically smothered out from finding no means of reënforcement.

Cases are on record where the whole larynx has been removed and a silver one substituted, so arranged that a simple reed could be inserted, and the patient could articulate just as well as before, with the sole difference that he spoke always on the same fundamental pitch. The system of phonetic writing devised by Alexander Melville Bell, by means of which an expert can represent perfectly any sound, articulate or inarticulate, by simply using a set of symbols that tells the speaker how to place the parts of the mouth, and how to use the breath and voice, is a practical proof that articulation proper is done above the larynx. Evidence in this case is also furnished by the methods of teaching deaf mutes to speak and to some extent by their ability to tell the meaning from the motions of the lips. Individual or race peculiarities of pronunciation may, of course, be due to peculiarities in the dimensions and character of the vocal cords and larynx, as well as to the cavities of the mouth and nose,

etc., but these elements are persistent and affect the voice accordingly.

The third and last element that must be considered under the physics of phonetics is the sound-receiving apparatus of the human being. The ear (q.v.) consists of three essentially different parts: the interior ear, where are situated the nerves which perform the actual hearing; the intermediate ear, consisting of a series of little bones which transmit the vibrations of the ear drum to the nerves within; and finally the drum and external ear. The drum takes up the vibrations which fall upon it, and transmits them to the nerves. All of these parts have little or no effect upon the quality of the sound perceived, provided the ear is well and normal. The external ear, however, acting as a collector of the air vibrations and concentrating them upon the drum, does to some extent act as a resonator and distort the quality of the sound produced. This is practically constant for an individual and is not noticed, but it may vary considerably in different individuals, and hence the same sound complex may seem really different to two individuals by the time it reaches the real hearing mechanism.

BIBLIOGRAPHY. The standard work is Sievers, *Grundzüge der Phonetik* (5th ed., Leipzig, 1901), which has a full bibliography. PHONETIC SPELLING. Spelling according to sound. See ORTHOGRAPHY; SHORTHAND; SPELLING REFORM.

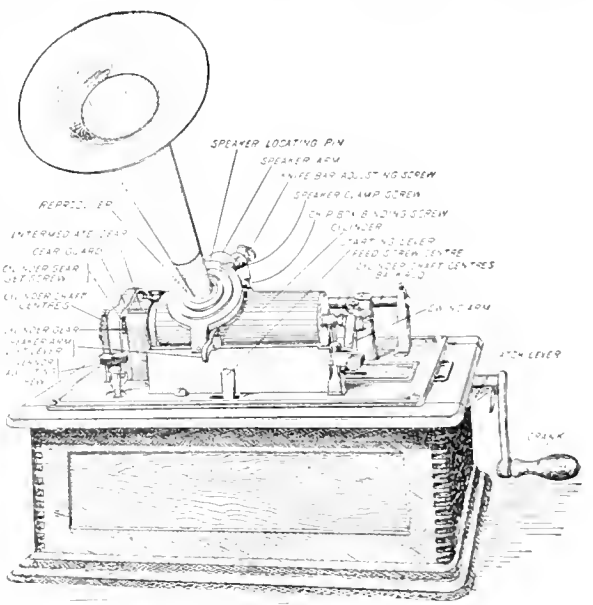
PHONETIC WRITING. Writing according to sound. In the case of languages which have not previously been reduced to writing and thus acquired a stereotyped orthography, phonetic writing is necessarily regularly employed. In this way many Polynesian, African, and American Indian dialects have received a written form. In languages which already possess an established orthography, phonetic writing is employed either in shorthand or in so-called spelling reform. In the former case the phonographic shorthand signs are afterwards transliterated into the conventional orthography. In the latter instance the sound as heard by the writer is preserved at the expense of the etymology and very frequently of consistency, the same word often being variously written in phonetic spelling by different writers, and with a more or less cumbrous system of arbitrary diacritical letters. In indicating the exact pronunciation of words whose orthography does not represent the sound, some exact system of phonetic writing is usually employed. See ORTHOGRAPHY; SHORTHAND; SPELLING REFORM.

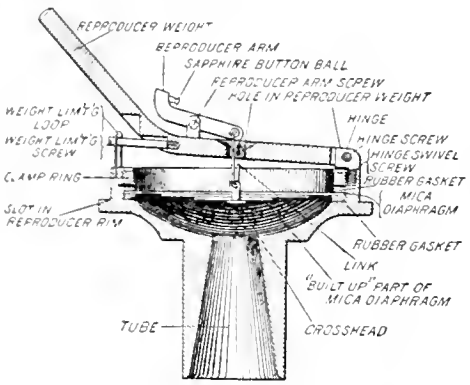
PHONOGRAPH (from Gk. *φωνή, phōnē*, sound, voice + *γράφειν, graphein*, to write). The first mechanical device for the registering and reproduction of speech or other sound was the invention of Leon Scott, known as the phonautograph and constructed in 1855. It consisted simply of an ellipsoidal barrel. In this apparatus the sound receiver was open at one end and closed at the other. From the closed end projected a



EDISON PHONOGRAPH.

small tube, across which was stretched a flexible membrane, to the centre of which by means of sealing wax was affixed a bristle, which acted as a stylus, and vibrated with the membrane. In front of the membrane was placed a horizontal cylinder, which was wrapped with a sheet of paper, covered with a thin layer of lampblack, against which the bristle rested lightly. Any sound vibrations entering the ellipsoid were transmitted by the membrane to the stylus, which, when the cylinder was made to revolve, and to advance slowly, described on the lampblack surface a zig-zag line which was thus practically a phonographic record of whatever vibrations had been produced.

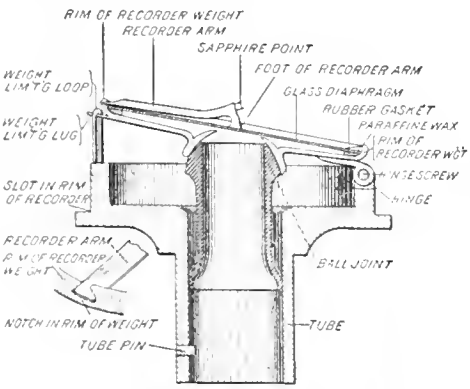
The invention of Leon Scott embodies the essential principles on which recording and reproducing instruments of the present day are based. It now we substitute a receiving funnel for the ellipsoid, a more rigid or metal stylus for the bristle, and a tin-foil covered cylinder for the lampblack one, we have the phonograph of Thomas A. Edison, as it was originally constructed in 1877; with this essential difference, however, that the sound vibrations were now indented instead of being traced. By reversing the machine—that is, causing a blunt stylus to travel over the indentations made, the original sound was reproduced. Great expectations were entertained of this invention at the time; but it



SECTION OF REPRODUCING APPARATUS OF EDISON PHONOGRAPH.

was found that after a few repetitions the record became effaced from the tin foil and the invention proved to be scarcely more than an interesting toy.

During the year 1888 Mr. Edison placed upon the market a phonograph which was a far more elaborate machine as well as more practical than any of its predecessors. The tin-foil gave place to a wax cylinder, which, as shown in the illustration, is slipped over and held on a mandrel. The recording and reproducing devices differ slightly and are shown in the accompanying figures. In operating, the wax cylinder is made to revolve. In talking into the funnel, the malle-



SECTION OF RECORDING APPARATUS OF EDISON PHONOGRAPH.

able glass diaphragm, with a cutting stylus on its under surface, is made to vibrate, and a register of the sound is thus cut vertically into the wax, the cutting stylus advancing horizontally as the cylinder revolves. In reproducing, another diaphgram, which differs from the first in that it has a different tool and is made of sheets of mica, is employed. The cutting or recording stylus consists of a sapphire with a cup-shaped front which is ground to a fine edge. The reproducing stylus, on the other hand, has a ball-shaped point. This stylus follows the track cut out by the recording stylus. Its motion causes the diaphragm to vibrate, and thus to reproduce the original sound. The machine gets its power from a small electric motor or spring. The sound thus reproduced is not at all equal in volume to the original, but may be strengthened by means of a funnel attached to a reproducer, and by adjusting the speed of the machine sounds may be given out with sufficient loudness to be heard by all in a room. In using a cylinder that already contains a phonographic record, a sharp knife precedes the cutting stylus, thus removing the previous record. A record once made can be reproduced several thousand times without perceptible impairment of its quality, and a record made on one machine can be reproduced on another, thus admitting of the cylinder's being used for mailing, as in ordinary correspondence. There is no limit to the speed with which sounds can be recorded, nor to the number and variety of sounds. The difficulty of concentrating the sounds upon the diaphragm is surmounted in factories where musical and other records are constructed by grouping together the persons or instruments whose sound is recorded. By increasing the speed of the cylinder the pitch is raised, and by lessening it the pitch is lowered. See GRAMOPHONE.

PHONOGRAPHY. See SHORTHAND.

PHO'NOLITE (from Gk. *φωνή, phōnē*, sound, voice + *λίθος, lithos*, stone). An igneous rock of porphyritic texture which has a chemical composition essentially equivalent to nephelene syenite (q.v.), and generally contains porphyritic crystals of feldspar (sanadine) and nephelene. Most phonolites have been poured out at the surface of the earth as lavas; as, for example, in the Auvergne of Central France, and in the Cape Verde Islands. Many phonolites possess a platy parting or separation by cracks into a series of parallel plates, so that they give out a peculiar sound when struck with a hammer. On this account they were formerly known as clinkstones. More subject to alteration from atmospheric agencies than most other rocks, they soon lose their fresh appearance, and frequently show the development of crystals of the zeolite minerals.

PHO'RADEN'DRON. An American plant. See MISTLETOE.

PHOR'BAS (Lat., from Gk. *Φόρβας*). (1) A son of Lapithes and Orsinome, who freed Rhodes from snakes and was honored by the inhabitants as a hero. He was called *ophiuchus* (the snake-holder) and given a place among the stars. In another legend, Alector, King of Elis, secured his assistance against Pelops, and gave him his daughter, sharing the kingdom with him. (2) A companion of Æneas. The god of sleep assumed his form in order to deceive Palinurus.

PHOR'CUS, PHORCYS, or **PHORCYN.** In Greek mythology, an aged divinity of the sea. Hesiod and others make him the son of Pontus and Gæa, and brother of Nereus and Ceto. By

the latter he became the father of the Graces and Gorgons, who are hence called Phorcides or Phoreydes. He was also the father of the nymph Thoosa, who became the mother of Polyphemus, the Hesperides, and the Sirens.

PHORMIO. A lively and interesting comedy by Terence, produced in B.C. 161. It takes its name from the parasite in the play, which was modeled on the Ἐπιδικαζόμενος of Apollodorus. From this comedy Molière drew the plot of his *Fourberies de Scapin*.

PHORO'NIS (Neo-Lat., from Gk. Φορωνίς, relating to Phoroneus, from Φορωνεύς, *Phorōneus*, Phoroneus, an ancient Greek King of Argos). A marine worm-like animal recently decided to be in a class by itself (Phoronidea). It lives socially, each worm inclosed in a membranaceous or leathery tube. The body is long, slender, not segmented, and around the mouth is a crown of long delicate ciliated tentacles borne on a horseshoe-shaped lophophore. It is hermaphroditic, developing from eggs, and never asexually from buds. The larva is very remarkable: it is a modified trochosphere, and is called an 'actinotrocha.' It may be recognized by the large hood-like lobe overhanging the mouth, while there is a post-oral circle of large ciliated finger-like tentacles; it rapidly metamorphoses into the polyzoön-like adult. It occurs on the coasts of Northern New England and in Europe, while another species inhabits the Australian seas. Consult Harmer, *Cambridge Natural History*, vol. ii. (London, 1899).

PHORORHACHOS, fō'rō-rā'kōs (Neo-Lat., from Gk. φορά, *phorá*, motion, from φέρειν, *pherein*, to bear + ῥαχός, *rhachós*, brier). A gigantic extinct running bird of prey, skeletons of which are found in the Miocene deposits of Patagonia. It was about 8 feet in height and its skull was larger than that of a horse and armed with a strong hooked beak like that of an eagle. The wings were small and useless, and the legs long and strong and provided with powerful talons. It appears to have been a swiftly running bird, like the ostrich, though actually related to the herons. Consult Lucas, *Animals of the Past* (New York, 1901).

PHOSGENE GAS (from Gk. φῶς, *phōs*, light + -γενής, *-genēs*, producing, from γίγνεσθαι, *gignesthai*, to become), CARBONYL CHLORIDE, or OXYCHLORIDE OF CARBON, $COCl_2$. A colorless suffocating gas which is formed by exposing equal volumes of carbonic oxide and chlorine to the action of sunlight. If brought into contact with water, phosgene gas rapidly decomposes into carbonic and hydrochloric acids. It may be readily condensed to a liquid, boiling at 8° C. It is largely used in chemical laboratories, as it readily reacts with various substances, so that many organic syntheses can be carried out with the aid of it. It is also employed in the manufacture of certain coal-tar dyestuffs. Phosgene was first prepared by J. Davy in 1811, its name indicating that it was formed under the influence of light.

PHOSPHATES (from *phosphorus*) (in physiology). The following phosphates play an active part in the chemistry of the animal body.

Phosphate of soda occurs in three forms, Na_3PO_4, Na_2HPO_4, and in NaH_2PO_4, called respectively the basic, neutral, and acid salts. These are all soluble in water. By exposing the second of these salts to a red heat *pyrophosphate* of soda, $Na_4P_2O_7$, is formed, and by similarly treating the third, *metaphosphate*, $NaPO_3$, results. Phosphate of soda in one or the other of the above forms is a constituent of all the fluids and soft tissues of the body, and is especially abundant in the urine and bile. Pyrophosphate and metaphosphate of soda are found in the ashes of animal tissues after incineration, but they result merely from the action of heat on the neutral and acid salts. The salts of sodium are always associated with the corresponding salts of potassium, and what is said of the derivation, elimination, and physiological importance of the one is equally applicable to the other. The alkaline phosphates obviously are derived from the food, being either ingested as such or converted within the organism from other alkaline salts. Elimination is effected chiefly through the kidneys and intestinal canal. In the carnivorous animals, whose blood is much richer in phosphates than that of herbivora (the ash of the blood of the dog, for example, contains from 12 to 14 per cent. of phosphoric acid, while that of the ox or sheep does not contain more than from 4 to 6), these salts are carried off by the urine; but in consequence of the formation of free acids as products of the disintegration of the tissues, a portion of the base is abstracted from the originally alkaline phosphates, and a corresponding portion of phosphoric acid is liberated. The originally alkaline salt is thus rendered neutral or even acid; and the occurrence of the acid phosphate of soda, NaH_2PO_4, in the urine is thus explained. In the herbivorous animals, on the other hand, the urine contains no phosphates, the whole of the phosphoric acid taken in their food being eliminated by the intestinal canal in the form of the insoluble phosphates of lime and magnesia. Although the general distribution of the phosphates of the alkalies in the nutrient fluids (there is 40 per cent. of them in the ash of the blood-cells; 28.4 per cent. of phosphoric acid and 23.5 of potash in the ash of cow's milk; and about 70 per cent. of phosphoric acid in the ash of the yolk of egg) is in itself an indication of their importance, the exact nature of their functions is not completely understood. Liebig has specially drawn attention to the peculiar grouping of the acid and alkaline fluids of the animal body. The permanence of this grouping is chiefly maintained, especially in herbivorous animals, by the conversion within the body of alkaline and neutral phosphates into acid phosphates by the means already described. Moreover, all tissue-forming substances (the protein bodies) are so closely connected with phosphates that they remain associated during the solution and subsequent reprecipitation of these substances; and the ash of developed tissues (such as muscle, lung, liver, etc.) always affords evidence that acid phosphates existed in the recent tissue; and, further, no exudation from the blood-vessels can undergo transformation into cells and fibres, or, in other words, become organized, unless phosphates are present. Another proof of the share taken by the phosphates in the formation and functions of tissue is the fact that, although herbivorous animals take up a very small quantity of phosphates in their food, and although their blood is very poor in these salts, their tissues contain as large a proportion of phosphates as the corresponding parts of car-

nivera. Lastly, the fact that one equivalent of the alkaline phosphate of soda, Na_2HPO_4, possesses the property of absorbing as much carbonic acid as two equivalents of carbonate of soda, leads to the belief that the power of attracting carbonic acid, which the serum of the blood possesses, is due as much to the phosphate as to the carbonate of soda, and that, consequently, phosphate of soda plays an important part in the respiratory process.

Phosphate of lime occurs in the organism in three forms, viz.: as the normal calcium phosphate, $Ca_3(PO_4)_2$, the monocalcic calcium phosphate, $Ca(H_2PO_4)_2$, also called acid phosphate, and the dicalcic phosphate, $Ca_2(HPO_4)_2$. The normal phosphate occurs in all the solids and fluids of the body, but is most abundant in the bones, in which it amounts to about 57 per cent.; and in the enamel of the teeth, in which it ranges from 80 to 90 per cent. It may at first sight appear inexplicable how a salt so perfectly insoluble in water as normal phosphate of lime can be held in solution in the animal fluids. In some fluids, as the blood, it is probably, in part, at least, combined with albumen, with which it forms a soluble compound; while in other fluids, as the urine, it is held in solution by a free acid or by certain salts (as, for example, chloride of sodium), whose watery solutions are more or less able to dissolve it. When too small a quantity of this salt is taken with the food, the bones lose more or less of their hardness and firmness, and fractures do not readily unite. Phosphate of lime, like the phosphates of the alkalies, is indispensable to cell formation; and in the mantle of the mollusks (where new cells for the formation of shell abound) this salt is far more abundant than in any other part of the body. Although by far the greater quantity of the phosphate of lime found in the body has doubtless preëxisted in the food, yet it is unquestionable that a part of it is formed within the organism by the action of carbonate of lime on the phosphoric acid that is formed during the disintegration of the phosphorus containing tissues, such as the brain. In man and carnivorous animals, a certain portion of the phosphate of lime is eliminated by the kidneys, and the rest is carried off in the excrements; while in herbivorous animals the whole is carried off in the excrements. The acid phosphate of lime is occasionally found in the urine of man and carnivorous animals, but is of no practical importance. For the amount of earthy phosphates daily eliminated by the kidneys, see URINE.

Normal phosphate of magnesia, $Mg_3(PO_4)_2$, is analogous, both in its chemical and physiological relations, to the corresponding salt of lime, with which it is always associated. The abundance of this salt in cereals and vegetables explains its presence in the system. A far less amount of this salt than of the corresponding lime-salt seems to be required by the organism, as is shown by the relative quantities in which they occur in bone (.57 of the former to 1.3 of the latter), and as is further indicated by the fact that, relatively, far more of this than of the lime-salt escapes intestinal absorption, and appears in the excrements.

The only phosphates remaining to be noticed are the *phosphate of ammonia and magnesia*, or triple phosphate, $MgNH_4PO_4 + 6H_2O$, which occurs in beautiful prismatic crystals in alkaline urine and urine that is beginning to putrefy, and the *phosphate of soda and ammonia*, which is occasionally found as a crystalline sediment in putrid urine.

PHOSPHATIC DIATHESIS, or PHOSPHATURIA. The excretion in excessive amounts of the earthy salts of phosphoric acid in the urine. Phosphoric acid is excreted in combination with the alkaline bases, sodium and potassium, and the earthy bases, calcium and magnesium. The alkaline phosphates form about two-thirds of the whole, and are always held in solution; the earthy phosphates form about one-third and are spontaneously precipitated under certain circumstances as phosphatic deposits and calculi. One of the causes of such deposition is an alkaline condition of the urine. The urine in health may be temporarily alkaline from eating much fruit or vegetables containing citrates, tartrates, or malates of potassium and sodium. These are converted into carbonates in the intestines and absorbed as such into the blood, and diminish the acidity of the urine or render it alkaline. The urine is sometimes turbid from a white deposit of the amorphous calcium phosphate ($Ca_3P_2O_8$). This may be mixed with a crystalline phosphate ($CaHPO_4 + 2H_2O$), the so-called stellar phosphate, or a phosphate of magnesia ($Mg_3P_2O_8$). A more common condition, however, is that observed when a feebly acid or neutral urine is heated and a thick white deposit or turbidity occurs. In urine which has undergone ammoniacal fermentation there occurs a precipitate of the ammonio-magnesium or triple phosphate ($MgNH_4PO_4 + 6H_2O$), in the form of minute triangular prisms.

It has been thought that there is a relation between the activity of the nervous system and the excretion of phosphoric acid. An increased amount is seen in the urine after excessive mental work or worry. This phenomenon is also observed in many diseases characterized by wasting and debility, such as phthisis, leucocythæmia, acute yellow atrophy of the liver, and severe anæmias. The old term 'phosphatic diathesis,' signifying a constitutional tendency or habit of body that produced or promoted a deposition of the phosphates from the urine, is no longer recognized.

PHOSPHATIC FERTILIZERS. See MANURES AND MANURING.

PHOSPHINE. See PHOSPHORUS.

PHOSPHOR-BRONZE. An alloy consisting of copper, zinc, and tin in various proportions, with a small quantity of phosphorus which has been introduced in the form of phosphor-tin. The addition of phosphorus has the effect of eliminating the oxides, and, by causing the tin to assume a crystalline structure, increases the homogeneity of the alloy, and thereby its elasticity and absolute resistance. In consequence, phosphor-bronze has met with considerable demand where special strength or power of resisting wear is required, as in the case of bearings for quick-running machinery.

PHOSPHORESCENCE. It has been observed that many bodies continue to emit light in a darkened room after having been exposed to sunlight or some other strong source of light. This phenomenon is called phosphorescence. Although the name is evidently derived from 'phosphorus,'

it should be noted that the cause of the luminosity of phosphorus is a slow oxidation, and is not due to its having been previously exposed to light. Phosphorescence itself is a special case of fluorescence (q.v.), and cases where there are permanent chemical changes are excluded. Those substances which phosphoresce most brilliantly are the sulphides of barium, calcium, and other alkaline earths, diamonds, sugar, etc. It has been found that the phosphorescent light is often brilliantly colored, and also that the color of the light to which the body is exposed in order to excite phosphorescence has a very important influence upon the intensity of the phosphorescent light itself. It is observed that the same law connecting the exciting light and the phosphorescent light holds true as was noted in the case of fluorescence, namely, that the phosphorescent light is of a longer wave-length than the exciting light. A distinction has been drawn between phosphorescence and fluorescence from the fact that only fluids exhibit fluorescence, while only solid bodies exhibit phosphorescence. Nearly all bodies which show fluorescence will show phosphorescence when in the solid state, as, for instance, if when liquid they are dissolved in gelatin and then dried. One of the earliest and most important investigations of phosphorescence was made by E. Becquerel, who made a special study of the interval of time phosphorescence would continue after the phosphorescing body was removed from the light. He invented an instrument known as the phosphoroscope, which enabled him to measure with the greatest exactness the small intervals of time involved in the phenomena. He observed that many bodies in which by ordinary means of observation there was no trace of phosphorescence can be shown to phosphoresce for minute fractions of a second. For instance, after exposure to sunlight, calcite shines with orange-colored light; aragonite gives a greenish light, as does lead glass also; uranium glass shines with a greenish light which lasts for about one-thirtieth of a second, although it has its maximum intensity at about one three-hundredth of a second after the sunlight has been withdrawn. Sapphires and rubies give a brilliant pure red light, as do almost all the minerals which contain aluminum.

One most interesting feature of phosphorescence is that if a body is phosphorescing, as for instance a piece of paper covered with Balmain's paint, the application of heat at any one point will destroy the phosphorescence there. This evidently furnishes a method for the study of those portions of the spectra which lie in the infra-red region; i.e. those wave-lengths which are too long to affect our sense of sight. For if a strip of paper covered with Balmain's paint is exposed to sunlight for a short time and then taken into a darkened room and so placed that the infra-red spectrum coming from any source falls upon the paper, those places where there is radiation will be made manifest by the disappearance of phosphorescence owing to the heating effect of the rays of the spectrum. This procedure has been improved by Draper and Lommel, and now forms one of the best methods used in spectrum analysis. See LIGHT: FLUORESCENCE.

PHOSPHORESCENCE OF THE SEA. See LUMINOSITY OF ANIMALS.

PHOSPHORIC ACID, H_3PO_4. An acid compound of phosphorus, hydrogen, and oxygen, first obtained by Scheele in 1777. It may be prepared by cautiously heating yellow phosphorus with dilute nitric acid for several hours and driving off the excess of nitric acid by heat. Pure phosphoric acid is a colorless crystalline substance melting at about 41° C. It is a tri-basic acid, the three hydrogen atoms in its molecule being replaced gradually and the result being three series of salts, like NaH_2PO_4, Na_2HPO_4, and Na_3PO_4. The 'neutral' salts of the alkali metals have a strongly alkaline reaction. When heated above 300° C. phosphoric acid is converted into pyrophosphoric acid, $H_4P_2O_7$, which was first prepared by Gay-Lussac in 1829. Several of the salts of phosphoric acid are used in medicine. The most important phosphates are described under the names of the metals. See also PHOSPHORUS.

PHOSPHORITE. The massive, concretionary, and mammillary form of apatite, especially the variety found in Estremadura, Spain. The name was first used by Kirwan in describing the phosphates found in Spain, which occur in veins and in pockets in the Silurian schists.

PHOSPHOR'OSCOPE (from Lat. *phosphorus*, Lucifer, phosphorus + Gk. σκοπεῖν, *skopein*, to behold). An apparatus invented by Becquerel for measuring the duration of phosphorescence in different bodies. See PHOSPHORESCENCE.

PHOSPHOROUS ACID, H_3PO_3. A di-basic acid formed by the action of water on trichloride of phosphorus. It is a crystalline substance melting at 70° C. Its salts are termed phosphites.

PHOSPHORUS. One of the non-metallic chemical elements. It was discovered by Brand, a Hamburg alchemist, in 1669, while experimenting with urine with a view to preparing a liquid for the transformation of silver into gold. Kunckel, on learning of the discovery, without, however, knowing the method, invented a process of his own for the extraction of phosphorus from urine, and in 1678 published a work entitled *De Phosphoro Mirabili*. The existence of phosphorus in bones was discovered either by Gahn (about 1769) or by Scheele (1771), and subsequently phosphorus became a well-known and cheap substance, variously called Brand's phosphorus, Kunckel's phosphorus, Krafft's phosphorus, Boyle's phosphorus, and English phosphorus, while the name phosphorus, unqualified, was applied to phosphorescent substances in general until the antiphlogistic nomenclature introduced the present usage. The elementary nature of phosphorus was first recognized by Lavoisier. See CHEMISTRY.

Phosphorus does not occur free in nature, but is found abundantly in the form of phosphates. The minerals of the apatite group (combinations of calcium phosphate with calcium chloro fluoride), struvite, vivianite, wavellite, and many other minerals contain considerable amounts of chemically combined phosphorus. But the principal source of phosphorus is still the substance of bones, which consists chiefly of the neutral phosphate of calcium. Calcium phosphate is also the chief constituent of coprolites and guanos, and calcium and magnesium phosphates are found in the ashes of plants. Ammonium-magnesium phosphate is the chief constituent of urinary sediments, while in combination with carbon, hydrogen, oxygen, and nitrogen, phosphorus is found in

the yolk of eggs, in the blood and other animal fluids, and in the substance of the brain and nerves.

To obtain phosphorus, bones are burned to destroy their organic matter and are treated with sulphuric acid, which converts the neutral phosphate $Ca_3(PO_4)_2$ into the soluble acid phosphate, $CaH_4(PO_4)_2$. The solution of the latter is evaporated to dryness, charcoal is added to the residue, and the mixture is strongly heated, when two processes take place in immediate succession, the first consisting in the transformation of the acid calcium phosphate into calcium metaphosphate, $Ca(PO_3)_2$, the second in the partial decomposition of the metaphosphate by the charcoal, resulting in the formation of free phosphorus, some neutral calcium phosphate, and carbonic oxide gas. The phosphorus vapors are condensed under water in suitable vessels of clay. The crude product thus obtained may be somewhat purified by melting under water and pressing through porous plates. Arsenic, an impurity usually introduced with the sulphuric acid employed in the manufacture of phosphorus, may be removed by means of nitric acid. When pure, the phosphorus is melted and cast in the form of sticks by sucking it into glass tubes and allowing to solidify.

The chemical symbol of phosphorus is P; its atomic weight is 31. The properties of free phosphorus are not always the same, the element being capable of existing in several different allotropic forms. (See ALLOTROPY.) The vapor of phosphorus has invariably the same density, leading to the molecular formula P_4. (See MOLECULES, MOLECULAR WEIGHTS.) Experiment leads to the view that when dissolved in benzene phosphorus has a similar constitution. But the remarkable differences between the liquid and the several solid modifications of the element are by no means understood. Common or yellow phosphorus, which is ordinarily obtained by the manufacturer, is a transparent waxy substance that may be prepared in the form of crystals of the regular system by sublimation or by crystallization from solutions in carbon disulphide, in which the other varieties of phosphorus are insoluble. Its melting point is 44.5° C. and its specific gravity at 0° C. is 1.837. It phosphoresces in the dark, and although it has been shown to exhibit this phenomenon when kept in gases incapable of reacting with it, it is quite certain that in all such cases the phosphorescence is caused by the presence of traces of oxygen, which oxidizes yellow phosphorus very readily. As a matter of fact, when kept in a vacuum or in gases which have been thoroughly freed from oxygen, phosphorus gives off no light. In the air, at ordinary temperatures, yellow phosphorus undergoes slow oxidation (see OZONE), and may readily take fire even if carelessly rubbed. It may be caused to burn under water by gently warming the latter and passing a current of oxygen into it. Besides, yellow phosphorus is extremely poisonous. It must therefore be handled with great care. The use of phosphorus for matches is well known. (See MATCHES.) *Red phosphorus* was discovered by Schrötter, of Vienna, in 1845. It is gradually formed by the action of light, especially violet rays, on common phosphorus, but may be conveniently prepared by simply heating the latter to about 250° C. (450° F.), in an atmosphere of carbonic acid, nitrogen, or some other inert gas. If heated to about 300° C., red phosphorus is reconverted into the common yellow modification. The specific gravity of red phosphorus is about 2.14, and it does not melt. It does not phosphoresce in the dark, is not poisonous, and is in every way perfectly harmless. (See MATCHES.) *Crystalline* ('metallic') *phosphorus* is formed during the solidification of molten amorphous phosphorus. It may be obtained in the form of long red tabular crystals having a distinct metallic lustre. Its specific gravity is 2.34. *Black phosphorus* is formed when melted yellow phosphorus is rapidly cooled. Two other allotropic varieties of phosphorus have been described, but deserve no mention here.

COMPOUNDS OF PHOSPHORUS. Phosphorus forms at least three different compounds with hydrogen: viz. a solid hydrogen phosphate, P_4H_2; a liquid phosphide, P_2H_4; and a gaseous phosphide, PH_3, called *phosphine*. The last-named compound, analogous to ammonia (NH_3), is usually prepared by heating phosphorus with a strong solution of caustic potash. When thus prepared, however, it contains some vapor of the liquid phosphide, P_2H_4, and as the latter takes fire spontaneously in the air, the impure phosphine, too, is inflammable. But under the influence of light, or by the action of strong hydrochloric or sulphuric acid, and certain other substances, the vapor of the liquid phosphide is decomposed; and if pure phosphine is prepared, say, by passing the impure gas through concentrated hydrochloric acid, it is found not to take fire in the air. The odor of phosphine resembles that of garlic and of rotten fish. The *oxides* of phosphorus include phosphorus trioxide, P_2O_3, and phosphorus pentoxide, P_2O_5. The latter, usually termed 'phosphoric' anhydride, is formed when common phosphorus burns in the air. It forms a white, exceedingly hygroscopic powder, taking up water with great energy to form phosphoric acid. With the *halogens* phosphorus forms a trichloride, PCl_3; a pentachloride, PCl_5; a tribromide, PBr_3; a pentabromide, PBr_5; and a tri-iodide, PI_3. All these compounds are formed by the direct union of the elements. A tri-fluoride, PF_3, and a penta-fluoride, PF_5, are also known.

Phosphorus is a constituent of many tissues, especially the nerve-centres, and its physiological action is that of a tonic. It is chiefly used in medicine in nerve exhaustion, myelitis, neuralgia, osteomalacia, and rickets. It has been used with success in lupus, acne, and psoriasis. It may be given in pill or in solution, the latter being preferable. It may be exhibited dissolved in oil or in chloroform. Phosphide of zinc has been used as a substitute for phosphorus. See ANTIDOTES.

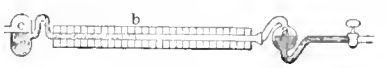
PHOSPHORUS (Lat., from Gk. *Φωσφόρος*, light-bringer). A name of the planet Venus as the morning star, also called Lucifer. As an evening star it is called Hesperus and Vesper.

PHOTIUS, fō'shī-ŭs (Lat., from Gk. *Φώτιος*) (c.820–c.891). Patriarch of Constantinople, one of the greatest theologians and scholars of the Greek Church. He was a member of a patrician family of Constantinople, and during the first period of his life filled various important public offices. In 857 Bardas, minister of the young Emperor, Michael III., undertook to remove the Patriarch Ignatius (see IGNATIUS, SAINT) from his position, and Photius, after being hurried through all the clerical offices in a few days, was put in his place. Pope Nicholas I. (q.v.) espoused the

cause of Ignatius and excommunicated Photius in 863. The latter maintained his position, supported by the Court, and in 867 assembled a council at Constantinople which excommunicated the Pope and his partisans, and withdrew from communion with the See of Rome. (See GREEK CHURCH.) The same year Basil I. succeeded Michael as Emperor, Photius was deposed and Ignatius reinstated. Ten years later, after the death of Ignatius, Photius was restored, and the Pope, John VIII., was induced to acquiesce; but in 881 he also excommunicated the Patriarch, whose relations with Rome continued unfriendly the rest of his life. In 886 the Emperor Leo banished Photius to an Armenian cloister, and he died there about five years later. Photius is revered by the Greek Church, while the Western Church accuses him of craft, violence, and perjury. His theological works include the *Amphilochia*, which not only discusses doctrinal and exegetical questions, but treats also of philosophy, science, medicine, grammar, and history; commentaries on the Gospels and Epistles; and a treatise in favor of the Greek doctrine of the procession of the Holy Spirit. The *Nomocanon* ascribed to Photius is of doubtful authorship. His chief literary and scholarly work is the *Myriobiblion* or *Bibliotheca*, a summary review of nearly 300 works which he had read, most of which are now lost. He also wrote a *Lexicon*, for use in reading the classic authors and the Scriptures. A number of Photius's letters are preserved, as well as sermons of much merit. His works are in Migne, *Patrologia Græca*, ci.-cv. Consult: Hergenröther, *Photius, Patriarch von Constantinopel* (3 vols., Regensburg, 1867-69); id., *Monumenta Græca ad Photium Spectantia* (ib., 1869).

PHOTO-CHEMISTRY. The branch of general chemistry that deals with chemical changes immediately producing or caused by light. In interpreting this definition it must be borne in mind that the combustion of illuminants cannot properly be classed as a form of photo-chemical changes, for the reason that combustion transforms the chemical energy of the illuminant, primarily not into light, but into heat, the latter then giving rise to the production of light. The chemical changes immediately producing light include those undoubtedly taking place at ordinary temperatures in the fireflies and other luminescent organisms, as well as in the eye. All such changes are as yet very imperfectly understood, and photo-chemical research has been confined almost exclusively to the opposite phenomenon, i.e. to chemical changes caused by light.

ACTINOMETRY. That light is capable of causing chemical transformations was not unknown in the eighteenth century. That silver chloride turns dark under the action of light was known to Schultze as far back as 1727. In the latter part of the century it was recognized that sunlight enables plants to decompose carbonic acid gas and set free its oxygen, and about 1840 Liebig grasped the full importance of this process in the economy of nature. But all photo-chemical knowledge remained qualitative until John W. Draper, of New York University, about 1842, introduced the quantitative measurement of the chemical action of light, by constructing the first 'actinometer.' Gay-Lussac and Thénard had observed in 1809 that a mixture of equal volumes of chlorine and hydrogen, which may be preserved indefinitely in the dark, reacts with explosive rapidity if exposed to intense light, and slowly if the light is weak. The product of the reaction is hydrochloric acid gas, which is freely soluble in water, while hydrogen and chlorine are soluble only sparingly. To measure the effect of light in causing the reaction, Draper introduced a mixture of precisely equal volumes of hydrogen and chlorine into a glass bulb (*a*) half



DRAPER'S ACTINOMETER.

filled with water and joined to a glass tube (*b*) likewise filled with the gaseous mixture, provided with a scale, and in its turn joined to a wide vessel (*c*) filled with water. He then exposed the upper part of *a* to light, whereupon part of the hydrogen and chlorine combined into hydrochloric acid, the latter was absorbed by the water, and the consequent diminution of the gaseous volume was shown by the length of the column of water entering from *c* into *b*. Draper's actinometer was improved in 1862 by Bunsen and Roscoe. But even the improved form of the apparatus did not permit of sufficiently rapid experimentation, and consequently the method was soon abandoned. Instead, Bunsen and Roscoe employed an actinometer which measured the chemical intensity of light by the time required to darken a photographic film to a certain standard degree.

In 1879 Eder devised a new method of actinometric measurement. If a mixture of mercuric chloride (corrosive sublimate) and ammonium oxalate in aqueous solution is exposed to the action of light (especially the ultra violet rays), a chemical change takes place resulting in the precipitation of mercurous chloride (calomel), the quantity of which measures the chemical intensity of the light. Account must of course be taken of the fact that the amount of calomel precipitated not only depends on the intensity of the light, but is also influenced by the varying concentration of the solution during the experiment.

In 1897 Rigollot constructed an actinometer by immersing into a solution of common salt two copper plates whose surfaces were previously oxidized in the flame of a Bunsen burner, and exposing one of the plates to the light. If the two copper plates of this apparatus are connected by a wire, an electric current is found to flow from the dark plate toward the illuminated one, the intensity of the current being proportional to the intensity of the light, and hence being capable of serving as a measure of the latter. It may be observed that the principle of electrochemical actinometry was discovered as far back as 1839, by Becquerel, who found that a current passed between two silver plates covered with films of chloride of silver and immersed in dilute sulphuric acid if one of the plates was exposed to the light.

GENERAL PRINCIPLES. Passing now to the few known general principles of photo-chemistry, it must be observed first of all that while it was formerly believed that light of certain colors only ('actinic rays') was capable of chemical action, it is now generally admitted that chemical

changes can be produced by light of any wave-length whatever, including the infra-red and the ultra-violet rays. It is further generally admitted that if a substance is at all incapable of absorbing light, it is also incapable of undergoing photo-chemical changes of any kind. It is often possible, however, to increase the capacity of a substance for absorbing light, by mixing it with other substances which absorb light freely.

When light produces a chemical change, it naturally loses more or less of its original intensity, part of its energy being transformed into chemical energy. When, therefore, light passes through a medium in which it causes some chemical change, its intensity is diminished, first through purely optical absorption, and secondly through 'photochemical extinction.' Thus, for example, if light is passed through a given volume of chlorine gas, it is partly converted into heat and its intensity is found to have diminished by a corresponding amount. If now, in a second experiment, light of the same original intensity is passed through a mixture of chlorine and hydrogen, the intensity is found to have diminished by a greater amount than in the first experiment, owing to the photochemical combination of chlorine and hydrogen into hydrochloric acid. The absorption of light by the hydrogen gas present in the second experiment is small and may be left entirely out of account. In either experiment, the diminution of intensity may of course be measured by means of one of the actinometers described above.

In conclusion, it may be pointed out that if a given substance is capable of undergoing a chemical change both under the influence of light and without this agency, the change in the two cases need not necessarily be quite the same. Thus it has been proved that the decomposition of hydriodic acid takes place, under the influence of light, according to the equation

$$HI = H + I,$$

i.e. molecule after molecule of hydriodic acid is primarily decomposed into single atoms of hydrogen and iodine. On the other hand, if hydriodic acid is decomposed by heat, without the intervention of light, the decomposition takes place according to the equation

$$2HI = H_2 + I_2,$$

i.e. the molecules are decomposed in pairs, each pair yielding a molecule of hydrogen gas and a molecule of iodine.

PHOTO-ENGRAVING. The art of preparing, by means of the chemical action of light upon certain bodies, an engraved plate or block for printing. There are two forms of this as there are of manual engraving; namely, engraving in intaglio, in which the ink for printing enters the incised lines and remains there while the rest of the plate is cleaned off; and relief engraving, in which the ink is deposited upon the projecting parts of an engraved block or plate. In either case the paper takes the ink from the surface as in the printing of ordinary manual engravings. Photo-lithography, or the preparation by chemical effects of light of plane surfaces for printing, is treated under LITHOGRAPHY.

INTAGLIO PHOTO-ENGRAVING. This is known by the general name *photogravure*, a French term generally accepted in all languages. Heliogravure is a term which may be taken as the equivalent of photogravure, varying in meaning as does that more general term; but at different times the name heliogravure has been given to special patented or secret processes. Photogravure may have the appearance of pure line work, exactly as in manual line-engraving (q.v.), and it may have the appearance of tint or shade without line, nearly as in the case of mezzotint (q.v.). This form of the art has been carried to such perfection by some workmen, especially in France, that it is to be compared only to the finest and most artistical hand work, having in addition to that artistic charm an accuracy of reproduction which the manual work cannot pretend to. Thus in the large books on painting and monographs of special painters issued during the last twenty years, and especially the more recent ones, such as De Beruete's *Velasquez*, Yriarte's *Mantegna*, Lady Dilke's *French Painters of the Eighteenth Century*, Armstrong's *Gainsborough*, *Turner*, and other volumes, and the splendid catalogues of public and private collections, photogravures alternate with half-tone prints and other prints from photo-engraving plates, but the photogravures are distinguishable at once by the fineness of their texture (pure line in the one case and grain or texture in the other), in which no other process can approach them. In the case of line photogravure the facsimile of a drawing or of a print from an engraved plate may be so perfect to be indistinguishable from the original except by the most minute examination of an expert. Thus in the published work of Amand-Durand of Paris, the facsimiles of fine prints from the plates of Dürer, Rembrandt, Claude, Paul Potter, and other celebrated etchers and line engravers caused astonishment and doubt among collectors of prints when those facsimiles first appeared about 1870. Here was an unquestioned original Rembrandt, not a copy, as any student of Rembrandt would know, and yet it was printed upon modern paper. In all these processes, however, hand work has to be called in to complete the plate; and it is a general truth that the most artistic workmen produce the most perfect photogravures. In the case of Amand-Durand there was the peculiar advantage that the director himself was a skilled engraver before he undertook the photo-engraved process.

Gelatin treated with bichromate of potash is made insoluble under the action of light. Instead of gelatin some other form of albumen may be used, or asphaltum, which is found to answer equally well and to be cheaper. In making a photogravure in line a photographic transparency, or positive, of the drawing or print or picture or object which is to be reproduced is placed in contact with a copper plate coated with asphaltum or albumen mixed with a bichromate, and strong light is allowed to pass through the negative to the sensitized surface. Only those parts where the light passes through the negative with-

out interruption will be marked by complete insolubility of the gelatin; elsewhere the surface remains soft and capable of being dissolved away by washing. In this way the surface of the prepared plate affected by light is turned into a relief copy of the original. The plate is then etched by an acid, perchloride of iron, which eats it away exactly as in the case of ordinary etching (see ETCHING). When it is a line plate which is being prepared no other important steps are necessary; but when the plate is to be a tint plate or gradation plate without line and producing prints much like those taken from a mezzotint, it is usual to prepare the surface of the copper plate in the first place, by precipitating upon it a fine powder of resin or of resin and asphaltum in combination. This powdered surface prevents the complete access of the mordant to the metal exactly as in the case of aquatint (q.v.). The granular surface so obtained may be either coarse or indefinitely minute, this depending upon the character of the subject to be reproduced. In this way the reproductions of portraits by the greatest master of refined execution or landscapes of minute detail of most varied character may be reproduced with a perfectness of gradation equal to that of hand work in its highest perfection.

As it has become customary to illustrate costly books by means of large photogravure plates, so it has become usual to employ living artists of celebrity to make original monochrome pictures for such reproduction. These are sometimes produced in the more usual fashion by means of water-color work in bistre, sepia, India ink, or other one-colored pigment, but they are also made on a very large scale by oil painting upon canvas, exactly as in the case of paintings intended for exhibition or sale, except that they are worked in such gray or brownish-gray pigment as the painter and the photographer agree upon as convenient for the one and most easily adapted to the work of the other. Such monochrome paintings are often of considerable importance, and those collectors of works of art who have purchased them at the time of their production have considered them an important part of their possessions. It may be stated, also, that the improvements made in orthochromatic photography have made it possible to obtain very accurately the relative color values of the most difficult subjects, elaborate oil paintings, and the like.

The difficulty with the employment of photogravure in book work is the great cost, not alone in the production of the plates (for it is not uncommon to take two or three months in the perfection of a large plate), but of the printing, which has to be done on a hand press, and slowly, so that every separate impression, of which fifty may be bound up in a folio volume, will have cost a definite sum of money over and above the cost of the plates. It is on this account that modified processes are continually brought forward intended to produce plates from which the printing may be done more rapidly. There is, however, always the difficulty in printing from intaglio-engraving, that in order that the paper shall take the ink from the incised lines perfectly, leaving none behind, so that the design is reproduced in every minute particular by the raised pattern of ink on the paper, only a slow and painstaking process will serve.

A kind of photogravure has been introduced in which a screen is employed to make the grain exactly as in the case of the half-tone process described below. This, of course, if perfected, will tend toward much greater ease in rapid printing.

RELIEF PHOTO-ENGRAVING. This covers all those processes by means of which a surface is prepared like that of a wood engraving, the lines, points, and small surfaces which are to be reproduced upon the paper standing up in low relief from the background which is cut away. The level surfaces of these lines and points must be exactly true and uniform, all in one plane, except where it is deliberately lowered in one place or another in order that the block at that point shall press the paper less firmly and the ink impression show pale in contrast with other and blacker parts.

One of the most difficult of these processes is that called commonly the Gelatin Process, or, to distinguish it from others also depending upon gelatin, the 'swelled gelatin process.' It is an expensive process and one requiring the greatest care to employ it successfully, but its results are not very markedly inferior to that of photogravure which is not in distinct line. In fact, a good print made by this process may be often taken for a photogravure print of somewhat inferior excellence, without clear black and white, with a too uniform texture and a cloudy rendering of details. A sheet of glass is coated with a film of gelatin sensitized with bichromate of potash and exposed under a black and white negative. The film is then soaked in water and swells up where the opaque lines corresponding to the whites of the design protected the film, while the surface of the film corresponding to the black lines of the design do not swell. From the surface so produced a matrix is made, and from this another in a material such as wax, and, again, an electrotype of copper is made and mounted upon a block to give it the requisite stiffness and thickness.

The Woodbury type, the collotype, the artotype, the heliotype, the albertype, and many similar processes are all based upon the properties of certain resinous and glutinous substances, and their changes when submitted to light. Asphaltum, albumen, and gelatin are the three used.

The Half-Tone Process has resulted from the invention of the mechanical art of ruling lines of extreme fineness, of perfect uniformity in width, and at absolutely equal distances from one another. This, which was not practicable until within comparatively recent years, has now been developed so that plates of glass can be ruled in this way with minutely incised lines, two hundred or even three hundred to an inch. When two glass plates, each ruled with lines of this sort, for instance, diagonally across the plate, are brought together in such a way that the two sets of lines cross one another, the result is, as seen by transmitted light, a fine network of square or diamond-shaped mesh. The half-tone process depends upon this 'screen,' as it is called. The photographic negative is made by light passing through this screen, placed at a suitable distance in front of the sensitive plate, and the result is an image broken up into minute dots, easily seen with a magnifying glass. There is no absolutely continuous gradation of tint; but everywhere a

series of very small dots which constantly increase and decrease in darkness or intensity, conditioned upon the relative lights and darks of the subjects to be reproduced, and which are small enough to produce a general effect of uniform gradation. This negative reversed is placed in contact with a carefully prepared copper plate, the zinc is also used that has been coated with a preparation of fish-glue, bichromate of ammonia, albumen, and water. It is then exposed to the light and afterward washed in water, and those parts protected from the light by the dense portions of the negative will be washed out of the half-tones in due proportion. After burning in—that is, heating over a gas stove—the plate is all ready for etching, which is done in the case of a copper plate with perchloride of iron, or with zinc nitric acid.

The half-tone process requires less artistic sense and ability than, for instance, photogravure, but it requires the neatest handling, the most perfect delicacy of treatment, and it is often necessary for a good block that the acid should be applied in several consecutive 'rebitings' before the surface is perfect. In much of the finest work of to-day the highest lights and delicate tone gradations are very skillfully retouched by an experienced wood-engraver. Much of the re-engraving by hand, however, is clumsily done, and adds to the shortcomings of poor plates.

The special utility of the half-tone block is in this, that it can be printed with type. In order that this may be done, the metal plate is backed up by a block of wood of the right thickness, so that the surfaces of the prepared metal shall be exactly even with the front of the types. With reasonably careful work in the preparation of the stereotype plates and the like, a page may be printed of typography with pictures of full light and shade incrusted in it; the whole printed together, and that even on the power press.

The Line-Cut Process gives an exact facsimile of a drawing in solid or dotted black lines. Any drawing which an artist will make with a point, as of a pen, or a brush, and which does not include tints or half-tones, can be reproduced in exact facsimile. The process is similar to those described above. The light passing through the negative hardens the prepared surface, and the unsoftened stuff is washed away. In fact, this may be considered the original process from which the half tone process has been produced by natural evolution, that is by the development along obvious lines. The linecut block can be used in connection with type exactly as half-tones at a very much less cost and with greater facility and less care in the manipulation.

Colored Printing from Photo-Engraved Surfaces. The most important process of this kind is that known as the Three-color Process. This has become a very familiar and widely used process and promises well. The system is based upon the scientific fact that all the colors of the spectrum may be obtained from the three primaries, red, blue, and green. The rays of light are separated by means of what are called photographic filters, which are partly transparent substances which allow particular rays to pass while they stop or restrain others. Thus one of the three filters will allow only blue rays to pass. By this appliance used in connection with the half-tone process there may be produced a perfect blue picture, and again with the use of other filters a green and a red, or approximately red picture. The printing of all these, one upon another, approximates very closely the complete chromatic result desired, that is to say, a picture in full color. The chief difficulties of the process are in the making of correct negatives, accurate registration in printing, and appropriately colored inks. The result so far may be said to approximate to the reproduction of fine manual painting. One obvious reason for this imperfection of the result is found in the inferior effect of colors superimposed to those which are laid side by side. Every student of painting knows how much more brilliant a gradation can be procured by putting touches of color close together, side by side, than by laying those colors over one another. It is true that much work, especially in oil painting, is done by superimposed color, but this is when the upper coat of pigment is more or less translucent, as when the yellow below shows through the thin glaze of blue to produce a certain quality of green. Commonly the juxtaposition of color is more brilliant than the superimposition of color; and this fact causes an indefinitely great amount of thought and experiment among those who are trying to improve the three-color process.

Another and more complex process of photographic color work has been introduced in the United States within the last four years, and some of the results are surprisingly accurate reproductions of the originals. The greatest successes in the color work have been obtained in the reproduction of colored textiles, notably in imitating the richness of color and texture of Oriental rugs. This is a secret process, and the methods employed are very carefully guarded. It is something more than the ordinary three-color work, and apparently as many as seven colors are employed in some cases. It is as yet costly.

PHOTOEPINASTY (from Gk. *φῶς, phōs*, light + *ἐπί, epi*, upon + *ναστός, nastos*, solid, from *νάσσειν, nassein*, to press close). The action of light in accelerating the growth of the upper sides of dorsiventral organs, such as leaves. *See* Growth.

PHOTOGRAPHIC SURVEYING (from Gk. *φῶς, phōs*, light + *γράφειν, graphein*, to write). In recent times the art of photography has found its way into surveying, an application due chiefly to the French. Its advantage was at once recognized for military and topographical purposes, but its usefulness for accurate and extensive surveys is still quite limited, owing to the imperfections of the photographic lens. The chief instrument is a view camera provided with cross-wires and an apparatus for leveling. A survey is effected by selecting at least two stations, and measuring the base-lines between them. Then at each station a series of plates are exposed, the camera being turned at each successive exposure sufficiently to obtain for the series a continuous photograph of the area to be surveyed. The method of executing a map and of calculating heights and distances from photographs is best obtained from works on the subject, but a general idea may be gained from the following. Since the images of the cross-wires are photographed on the plate, every point of the field

appears in its proper position in relation to the four quadrants of the plate. Thus in Fig. 1 IIII'

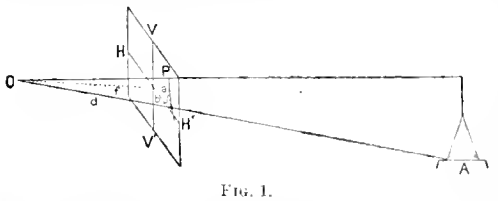

FIG. 1.

is the image of the horizontal wire, VV' the image of the vertical wire, and P the image of a church spire. The lines *a* and *b* can be measured in the photograph, and the focal distance *f* being known, line *d* can be computed, and when the distance OA has been determined from the map, the height of the spire above the level of the instrument is given by similar triangles. To plot a survey, the angular distance of any point from the base-line is determined by a photograph taken at each end of the base. In Fig. 2, P represents the plate of the camera at station A; B', C' being the images

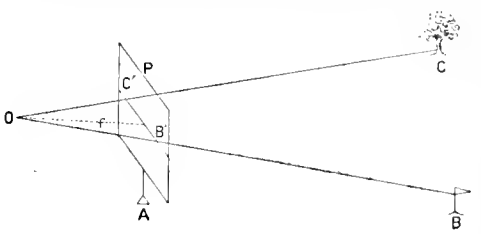

FIG 2.

of station B and the point C: the angle B' OC' can be determined from B' C' and the focal length *f*. Then any point of the map may be plotted as follows: Lay off the base-line to a desired scale, and draw lines making angles with the base equal to those computed. These will intersect in a point on the map corresponding to the point in the field. Consult Deville, *Photographic Surveying* (Ottawa, 1895). See SURVEYING.

PHOTOGRAPHY. The art of producing the appearance of objects and fixing them by means of light on a previously sensitized surface, and the reproduction of the image thus obtained, by various processes, on glass, paper, and other materials. The first photographic camera was in reality a darkened room to which light was admitted through a single small hole in the window shutter. This was the camera obscura of Giambattista della Porta, an Italian philosopher, invented by him in the last half of the sixteenth century. When the sun shone brightly, a faint inverted image of a landscape could be seen on the whitened surface of the wall within. The camera obscura of the present time differs very little from Porta's invention except that it contains a lens in the apex of the roof, with a reflecting mirror above it, in order to throw the light from all the surrounding landscape down through the lens and thus form a panorama on the surface of a table placed in the middle of the room. J. H. Schultze, a German, who has been called 'The Columbus of Photography,' obtained the first actual photographic copies of writing as early as 1727, by placing the written characters upon a level surface previously prepared with a mixture of chalk and silver nitrate. The rays of light passing through the translucent paper blackened the silver compound underneath, except where it was protected by the opaque ink forming the letters themselves, and thus a white copy upon a black ground was obtained.

Scheele in 1777 demonstrated that silver chloride became black quickest by the action of the violet rays of the solar spectrum, thus showing that the rays of light were not equally active. A few years later Professor Charles projected the shadow of a head by means of strong sunlight on a sheet of white paper which had been made sensitive by chloride of silver and obtained a white profile on a darkened surface; but he was unable to fix the image upon the sensitive paper. Meanwhile the members of the Lunar Society, including Samuel Parr, James Watt, Josiah Wedgwood, and others, met regularly at the house of Matthew Boulton at Soho and discussed their experiments, some of which were on the action of light, and it has been shown that an artist named Eginton, in the employ of Boulton, made and sold numerous copies of well-known paintings at very low prices. Thomas Wedgwood, to whom is due the honor of being the first to produce pictures by the action of light on a sensitive surface, published his paper giving "an account of the method of copying paintings upon glass, and of making profiles by the agency of light upon nitrate of silver, with observations by H. Davy," in the *Journal of the Royal Institute* for June, 1802. To Davy credit is due for his discovery that silver chloride was more sensitive than the nitrate; but, notwithstanding his continued investigations, Davy was unable to find a means by which the fading out of the pictures could be prevented. Other investigators took up the subject later, among whom may be mentioned Joseph Niepce and Daguerre in France, and William H. F. Talbot in England. The first-named, in 1814, succeeded in producing permanent pictures by a process which he called *heliography*. It consisted in coating with bitumen a piece of plated silver or glass, which was then exposed in a camera obscura during 4 to 6 hours. Those portions of the bitumen which were acted on by the light became insoluble, and by removing the parts unacted upon by certain essential oils in which bitumen was soluble, the shadows of the image were removed, and the lights were represented by the insoluble bitumen that remained on the plate. This process was therefore the forerunner of our modern photo-mechanical methods. In 1824 Daguerre began his experiments, which led to the invention of his celebrated process. He formed a partnership with Niepce in 1829, and ten years later they announced the invention of the daguerreotype process, the principle of which had been discovered by Daguerre in 1832. The process consisted in exposing a metal plate covered with silver iodide for twenty minutes in a photographic camera, after which the plate was transferred to a dark room and exposed to the vapor of mercury, which developed the latent image, the latter being then made permanent by means of a solution of sodium chloride. Sir John Herschel, who devoted considerable attention to this subject, soon after announced the greater suitability of sodium hyposulphite for dissolving the haloid salts of silver and consequently the hyposulphite was adopted as a

fixing agent. Daguerre received a pension of 6000 francs from the French Government on August 10, 1839, in consideration of which the details of his process were given to the world. Information of this invention reached the United States in 1839 through Samuel F. B. Morse, who communicated it to his colleague in New York University, John W. Draper (q.v.), by whom the first sunlight picture of a human face (that of his sister Dorothy Draper) was made in 1840. Meanwhile Talbot, in England, had been pursuing investigations from a different view-point, and on January 31, 1839, he presented before the Royal Society a paper on "Pathogenic Drawings." These he produced by dipping writing paper in a solution of sodium chloride, drying, and then transforming the sodium chloride into silver chloride by passing the paper through a solution of silver nitrate. With this paper, which was extremely sensitive to light, he was able to produce a negative that became black by the action of sunlight except where it was covered by some opaque object, which he desired to reproduce, and in turn from this negative, by another exposure, a number of positive prints could be obtained, which were fixed by potassium bromide. Two years later Talbot patented his 'calotype' process, in which the negative was obtained by coating the surface of the paper with silver iodide, then washing it over with a mixture of silver nitrate with gallic and acetic acids, after which it was exposed in a camera to the object he wished to copy. The invisible picture thus obtained was developed by silver aceto-nitrate and gallic acid, and fixed with potassium bromide. Minor inventions and improvements followed the introduction of Talbot's process, among which the most important was the use of albumen, recommended by Niepce de St. Victor as a film containing haloid salts which he flowed upon the surface of the glass.

The development of the modern rapid processes of photography may be said to have begun with the introduction of the dry collodion process by Scott Archer in 1851. This process consists in coating glass plates with a film of collodion containing soluble iodides or bromides, which form a sensitive silver compound when dipped in a solution of silver nitrate. The soluble collodion is prepared by the action upon cotton of a mixture of nitric and sulphuric acids with a little water, or of a mixture of potassium nitrate with sulphuric acid, the resulting substance being dissolved in a mixture of alcohol and ether. On evaporation, the viscous solution leaves a film of collodion. The exact proportions of the ingredients used must be varied at different seasons of the year, and must be suited to the character of the objects to be photographed, one variety being suitable for landscape views, another for portraiture, etc. The collodion is flowed over the glass plate, which must be perfectly clean, and when partially dry sensitized by dipping into a bath containing silver nitrate in the proportion of from 35 to 50 grains of the salt to an ounce of water. A very small quantity of potassium iodide is added to the bath. The sensitized plate is then exposed in the camera to the object to be taken. The action of the light on the sensitive silver salts changes them in such a way as to produce a latent image on the film, which is then developed by pouring over the plate a solution of ferrous sulphate or pyrogallic acid, to either of which are added some alcohol and acetic acid, after which the image on the plate is made permanent or fixed by immersion in a solution of sodium hyposulphite, potassium cyanide, or some other liquid capable of dissolving the portion of the silver salts that has not been acted upon by the light. For the protection of the collodion film it is common to coat the negative with a clear and hard varnish.

As the wet process required that the plates be prepared at the time of exposure, that process naturally found its most extensive employment for indoor work, and continual efforts were made to devise portable plates. Finally plates were introduced which were sensitized, washed, dipped in some organic preservative, such as a solution of tannin, and then dried.

In 1871 Maddox introduced the earliest form of the 'gelatin-emulsion process,' which has since been considerably improved, and is now used very largely. In this process the sensitive silver salt is held in suspension in either collodion or gelatin. The collodion emulsion may be made by dissolving in one portion of collodion a solution of zinc bromide, in another a solution of silver nitrate, and then thoroughly mixing the two portions. The gelatin emulsion may be prepared by bringing into solution the gelatin with potassium bromide, while a solution of silver nitrate to which some ammonia is added is gradually poured into the liquefied solution of gelatin. These emulsions are floated on plates and dried. Modern plates of this nature are found to be from ten to a hundred times more sensitive than the older wet plates, and have thus made possible the photography of moving objects and of those which are only dimly lighted. They also make possible the flash-light pictures by means of which instantaneous views are taken of a dark interior during the burning of a small quantity of magnesium. A large variety of developing agents are employed with the modern dry plate. Pyrogallic acid in connection with an alkali is perhaps the most common. Sodium hyposulphite is almost entirely used as the 'fixing' agent.

The camera consists of a box, either of wood or a framework of wood with a bellows-expanding body of leather, so that when closed the camera may occupy but little space and be conveniently carried. In the front of the camera is the lens, and at the back a piece of ground glass on which the image of the object to be photographed may be focused, together with an arrangement for lengthening or shortening the body of the camera. The camera should be placed so as to insure perfect rigidity when fixed, and for indoor work should be strong and steady, while for outdoor photography the camera stand should be made light so as to be easily portable, or the stand or tripod may be dispensed with altogether.

The lens is of very ancient origin. There is a lens in the British Museum which was found in the ruins of Nineveh, and during the Middle Ages the manufacture and properties of simple lenses were well understood in Europe. In general use now, four varieties of lenses are common: (1) A single lens consisting usually of a combination of two converging meniscus lenses separated by a diverging meniscus, arranged as a combination in the tube of the lens at the end nearest the camera, the convex side of the combination being toward the plate; (2) a rapid rectilinear lens consisting of a converging meniscus lens cemented to a diverging meniscus, the latter occupying the

outside position in the tube; (3) a wide-angle rectilinear lens of somewhat similar construction, having two combinations formed of meniscus lenses, but of much deeper curvature than those employed in other combinations, and placed closer together in the lens tube; and (4) the portrait lens, consisting of a back and front combination, arranged at some little distance apart, the front combination containing a double convex and a plano-convex lens cemented together, the double convex lens taking the position next the object, while the back combination consists of a double convex and a diverging meniscus lens, which are frequently mounted so as to leave a small space between the two.

In photographing an object the camera is set up, and, after the image is properly focused on the ground glass plate, the holder containing the sensitized plates, which are carried in double-backed dark frames arranged to carry two plates, each back to back, is inserted in the camera and the cover of the slide is withdrawn, exposing the sensitized plate so that it receives the picture. The shutter is then closed and the cover of the dark slide placed over the plate, which is later taken to the dark room for development.

For the bringing out or 'developing,' as it is called, of the latent image that has been produced on the sensitive plate, it is treated with various solutions; thus, in the daguerreotype the vapor of mercury is the agent used, and in the wet collodion process, as has already been mentioned, the development is effected by ferrous sulphate or pyrogallic acid. In the case of the dry plates, a developer, prepared by adding one part of a saturated solution of ferrous sulphate to four parts of a saturated solution of potassium oxalate, to which has been added a very small quantity of a solution of potassium bromide, is sometimes employed. A ferrous citro-oxalate is frequently used instead. As the plates are exceedingly sensitive, they must be developed in a dull ruby light, and the operation is accomplished by laying the plate in the developing tray, face upward, after which the liquid is run gently from one end of the plate to the other. Excellent results have also been obtained by the use of hydroquinone, eikonogen, metol, etc. These substances, when mixed with potassium bromide and sodium sulphite to act as reducing agents, produce very clear negatives. But pyrogallic acid is still most largely used as a developing agent.

For the reproduction of printed copies from the negative, a paper sensitized by dipping in a solution of silver nitrate is employed, and is then exposed to the sunlight, under the negative. The paper, which should be of some light and moderately strong quality, is first coated on the surface with a smooth layer of albumen to which either ammonium or sodium chloride has been added, and then floated in a solution of silver nitrate of varying strength, according to the condition of the negative, and of which 50 grains of the salt for every ounce of water is an average proportion. The exposure to light also varies according to the brightness of the light and the character of the negative. The print thus obtained is toned by immersion in a neutral solution of gold containing certain metallic salts, and finally the image is fixed by immersing the print in a solution of sodium hyposulphite which removes the unaffected silver salt. The final operation consists in thoroughly washing the print, after which it is ready for mounting.

The gradual disappearance or fading out of prints made with silver salts led to numerous attempts to find satisfactory substitutes, and various metallic salts have been employed for the purpose of producing permanent prints, some of which are described in the following paragraphs:

Cyanotype or Blue Prints. The earliest of these is perhaps the one first described by Sir John Herschel, and consisting in the reduction of ferric salts by light. Solutions of 1 part each of ammonium ferric citrate and potassium ferricyanide in 8 parts of water are made separately and then mixed in a dark room. The paper or cloth is floated on this solution and exposed under a negative to the action of sunlight, and then thoroughly washed. This process is employed largely for copying plans by builders and architects, and the lines of the drawing appear white on a blue ground. It is much used on account of its cheapness and simplicity. A somewhat similar process, in which the ammonium ferric citrate is substituted by a solution of 1 part of uranium sulphate in 4 parts of water, yields a beautiful rich brown print.

Ferrotype, or Tintype. In this process a piece of sheet iron is japanned with black varnish and baked, after which it is sensitized with a collodion solution and exposed in a camera to the object, then developed and finally covered with some protective coating. See Ferrotype.

Platinotype. The substitution of platinum for silver, originally introduced by W. Willis, has found considerable favor, owing to the fact that the prints are both richer and more permanent than those made with silver salts. The original process consisted in sensitizing the paper with a mixture of ferric oxalate and a platinum salt. Exposure to light resulted in the reduction of the ferric salt to the ferrous state, and when the ferrous salt was in solution the platinous salt was reduced by it. By floating the exposed paper on a solution of neutral potassium oxalate, which is a solvent for ferrous oxalate, the platinum salt in contact was immediately reduced to the metallic state and the image built up. Such prints were fixed by immersion in dilute hydrochloric acid, which dissolved any ferric oxalate or calcium oxalate that might be present. A second process has been introduced in which the paper is simply coated with ferric oxalate containing a small quantity of mercuric chloride, which after exposure is developed by a solution of potassium oxalate with the platinum salt. A still more recent method is one in which the paper is sensitized with a mixture of the platinum salt with sodium-ferric oxalate and sodium oxalate, and under the influence of light and the moisture of the air the reduction of the platinum salt takes place in the printing frame. Excellent results have been obtained by toning silver prints with platinum, which yields rich brown and black tones.

Photo Mechanical Processes. Methods by which photographic impressions could be reproduced by mechanical means, and so used directly on the printing press, have naturally been sought for, and have been invented. Such processes depend for the most part upon the action of light on a gelatin film impregnated with a bichromate, generally of potassium or ammonium. The processes in question may be divided into two groups.

In processes of the first group, the picture is molded in gelatin and colored by a pigment. The group includes the Woodburytype or Photoglyph and the Stannotype. In the Woodburytype a sheet of bichromatized gelatin, a highly sensitized mixture of gelatin and potassium bichromate, is prepared and a thin film exposed under a negative to a strong light and then washed to remove the unchanged gelatin that was protected from the light by the negative, and finally dried. This film is placed upon a sheet of soft metal, usually lead, and forced into it by hydraulic pressure, producing a mold of the picture, in which the dark parts are in intaglio and the light ones in relief. This mold is then inked with a solution of warm gelatin colored with pigment, and a sheet of paper laid upon it, a strong pressure exerted in a horizontal press, the excess of ink being forced out by pressure. The print is then immersed in a solution of alum, which renders the picture insoluble. The Stannotype, which is a modification of the foregoing process, consists in substituting for the lead plate a thin sheet of tin-foil properly strengthened in the back by electrotyping material. In the photo-mechanical processes of the second group, the picture is printed with ordinary printing ink from a gelatin surface, from stone, from metallic relief surface, or from an intaglio copper plate. The 'collotype' or 'phototype' processes of this group, in which the picture is printed from a gelatin surface, are represented by the *Albertype*, invented by Joseph Albert, of Munich, in 1869. This process consists of coating a sheet of plate glass with a thin film of chromatized albumen and gelatin, which is then laid face down on black cloth and exposed to light. The insoluble gelatin next to the plate adheres firmly to the glass and serves as a foundation for a second film, which consists of chromatized gelatin. The dry film is placed under the negative in a printing frame and exposed to the light until the shades of the image are visible through the glass. Next the plate is washed in water to remove the soluble bichromate, and the film hardened with chrome alum and dried. The plate is fastened to the bed of a printing press by means of plaster of paris. The *Artotype*, which is similar to the foregoing, was invented in 1878. A mixture of albumen and soluble glass is used for the foundation on which the sensitive film is afterwards placed. As such a film does not require to be hardened by light opaque metallic plates may be used instead of a glass plate, as in the previous process. *Indotints* or *autoglyphs* are produced by processes similar to the foregoing, except that the support for the gelatin film is usually of copper slightly roughened in order to cause the sensitive film to adhere firmly. The addition of alcohol to the chromatized gelatin is said to increase the toughness and tenacity of the film. After exposure under the negative the unchanged bichromate is washed out and the plate is dried. Prints from such plates can then be taken on a power press. The heliotype process differs from the foregoing by the hardening of the gelatin film with chrome alum and the detaching of it from the support upon which it was first prepared; thus yielding, when completed, a thin sheet or skin of gelatin that is both tough and flexible, and which may be placed on a plate of zinc or attached to a cylinder when used for printing.

Excellent results in color have been obtained in the foregoing processes by preparing several gelatin plates, each of which corresponds to a different color in the original, and these are then used for printing with colored inks. Prints have been produced in which as many as seven successive distinct colors have been used. In those processes in which the picture is printed from stone, a sensitive mixture of albumen and ammonium bichromate in water is passed over a lithographic stone which has been thoroughly polished and cleaned. The excess is carefully rubbed off and the surface of the stone dried so as to remove all traces of moisture. It is then exposed under a negative, and wherever the light penetrates to the chromatized albumen it becomes insoluble. After sufficient exposure the surface of the stone is covered with lithographic ink and washed with water so as to remove the soluble parts of the film, and then treated with the acid and gummed and printed as in ordinary lithography. The difficulty in handling the heavy stones soon led to the invention of an improved process, in which a sheet of paper, sensitized with a solution of albumen, gelatin, and potassium bichromate, was placed face down on a sheet of smooth copper, and then exposed under a negative, after which it was coated uniformly with the usual lithographic transfer ink. The paper was then floated on boiling water in order to coagulate the albumen on the film, and the unaltered gelatin which was protected by the opaque portions of the negative absorbs moisture and swells, leaving the unaltered gelatin depressed. This print, again washed and then dried, is transferred to stone by simply placing it upon that material face downward and passing it through the press.

Processes in which the picture is printed from a metallic relief surface include the ordinary photo-engravings or photo-electrotypes. In the former a plaster mold is taken of the gelatin film and a cast reproduced in type metal, when it is called a *photo-engraving*, or in copper, when it is known as a *photo-electrotype*. These include those processes of photo-etching in which the pictures are printed from zinc plates to which the design has been transferred in adhesive transfer ink from paper, similar to the transfer process referred to under LITHOGRAPHY, section on *Photolithography*. The zinc plate thus obtained is then treated with acid in order to lower the white portions, producing a low relief.

Processes in which the picture is printed from an intaglio copper plate had their origin in France, and were known variously as *photogravures*, *photo-aquatints*, etc. These consist of gelatin relief films similar to those of the Woodburytype (see above), with certain modifications which caused the production of a grain in the relief film; thus in the case of the photogravures of Goupil, the material producing this effect is said to be pulverized glass. A mold is then made from the gelatin relief, from which a copper plate is obtained by electrotyping, from which the prints are then carefully made.

The invention of a transparent and flexible film pelliele for supporting the sensitized photographic surface was made by Hannibal Goodwin, and his application for patent was filed May 2, 1887, but the patent was not issued until September 13, 1898. The substance itself was entirely new, and the manufactured article consisted of a film support of a dried and hardened celluloidal solution of nitrocellulose. The film must be

non-greasy, insoluble in developing fluids, insensible to heat and moisture, hard, smooth, brilliant of surface, exceedingly thin and light, and absolutely transparent. It was no easy matter to obtain all these properties in the new support, and it is only after many years that the film has succeeded in supplanting, to any great extent, glass as a supporting substance. It was a very important invention and has made possible the widespread modern employment of photography by amateurs. The roll holder, by means of which a long strip of film can be carried in a comparatively small space, was first suggested by W. J. Stillman, and has led to the modern hand camera for films, and later to the so-called system of 'daylight photography,' which still further increased and simplified the use of photography by amateurs.

Applications of Photography. In addition to the production of pictures of persons and scenery, photography finds extensive application in reproducing paintings and thus popularizing famous works of art. Photography is further employed in many branches of science. The micro-photographs of minute forms of life have added much to our knowledge of such organisms, and the photographs of the heavens are furnishing innumerable data that will doubtless lead to astronomical generalizations of the greatest importance. (See Astro-Photography.) The application of photography in legal matters for the purpose of showing forged signatures and establishing facts that were disputed has been of the utmost value. Photographs taken from balloons during the Boer War furnished information that proved of great value. The biographic pictures in which the effect of motion is reproduced in consequence of the successive exposure, occupying but a 250th part of a second, has brought about a revision of the opinion in regard to many forms of motion, the details of which can now be studied. And the employment of photography is constantly growing.

Photography in Law. The courts have generally recognized that an accurate likeness of an object or place can be reproduced by means of the art of photography, and photographs are now often an efficient means of demonstrating a fact in the trial of a cause. They are admitted in both civil and criminal cases as an aid to the jurors in their efforts to understand descriptions of places and objects which might not otherwise be presented in an intelligible manner.

By the general weight of authority a photographer has no right to print copies from a negative likeness of a person, for his own use or distribution in any way, without the person's consent. The person whose likeness is thus taken may restrain the sale of his photographs, and recover such damages as he may have sustained by reason of the sale of the copies. This is generally placed on the ground of implied contract, and sometimes of breach of confidence. The photographer owns the negative, but the person whose likeness is on it has the right to say whether it shall be used or not.

Bibliography. The literature of photography is so extensive that mention can be made of but few of the many works dealing with the subject in its different aspects. In fact, many of the authorities have prepared a number of works each of which discusses a single process or phase of the subject, and these should be consulted by the reader in search of information. The works of Abney, Robinson, Vogel, Eder, and Burton are all authoritative and valuable. The following works will doubtless be of service to the reader, although it must be understood that such a list is by no means comprehensive:

Harrison, *History of Photography* (New York, 1887); Abney, *Instruction in Photography* (London, 10th ed., 1900); id., *Photography with Emulsions* (New York, 1886); id. (with H. P. Robinson), *The Art and Practice of Silver Printing* (London, 1888); Vogel, *Chemistry of Light and Photography* (London, 1882); Dallmeyer, *Telephotography* (London, 1899); Burton, *Photographic Optics* (New York, 1891); id., *Modern Photography* (London, 1892); Lummer, *Contributions to Photographic Optics*, translated and augmented by S. P. Thompson (London, 1900); Duchochois, *Photographic Reproduction Processes* (New York, 1891); Wilkinson, *Photo-Engraving in Line and Half-Tone* (London, 1886); id., *Photogravure* (London, 1890); Bolgas, Talant, and Senior, *A Handbook of Photography in Colors* (New York, 1900); Woodbury, *The Encyclopædia of Photography* (London, 1892); Wilson, *Cyclopædic Photography* (New York, 1894).

Among the more prominent English and American annuals may be mentioned: *The American Annual of Photography* and the *Photographic Times-Bulletin Almanac* (New York), and *The British Journal of Photography Almanac* (London). The principal current periodicals are the *Photographic Times-Bulletin* (New York), *Wilson's Photographic Magazine* (New York), *The Photo-Miniature* (New York), *Camera Work* (New York), *Camera Notes* (New York), *The Photo-Beacon* (Chicago), *Camera Craft* (San Francisco), *The Professional and Amateur Photographer* (Buffalo), *The Photo-Era* (Boston), *The British Journal of Photography* (London), *The Amateur Photographer* (London), *Photography* (London), *The Photographic Art Journal* (London).

PHOTOLITHOG'RAPHY. See Lithography, section on *Photolithography*.

PHOTOM'ETRY (from Gk. φῶς, *phōs*, light, + -μετρία, *-metria*, measurement, from μέτρον, *metron*, measure). The science of comparing the intensities of sources of light. It is impossible at the present time to measure the intensity of a source of light in terms of any absolute standard, i.e. in terms of watts; and therefore it is customary to compare the intensity with that of a standard source of light, and for this purpose various standards of white light have been proposed and used, but none have been completely satisfactory. These will be found discussed below. The 'intensity' of any source of light is defined to be the amount of light emitted through a cone whose solid angle is unity. The 'flux of light' is the amount of light emitted through any sized solid angle. The 'illumination' of any illuminated surface is the flux of light falling upon it divided by its area. The 'brightness' of a source of light, if it is a surface, is the intensity divided by the area of the surface. See an article by Crew, *Astrophysical Journal*, vol. vii., p. 298, 1898.

If a surface is illuminated by a small source of light, its illumination varies directly as the intensity of the source and inversely as the square of its distance from the surface. (See Light.)

intensity of two sources may be compared, by first allowing two portions of the same surface to be illuminated by them. If the illumination over these two portions is the same apparently to the eye, the intensities of the two sources are in the same ratio as the squares of their distances from the surface. There have been several devices invented to secure the illumination of two portions of the same surface by the two sources. These instruments are known as photometers and are described below. The problem of comparing two colored sources of light, or of comparing the intensities of the colors produced by two sources of white light when dispersed by a prism, is practically the same as that just discussed, but requires a photometer adapted for this purpose. See SPECTROPHOTOMETRY.

PHOTOMETERS. Most photometers are based upon the law of the inverse squares and enable us to compare the relative intensities of two lights by finding at what distance they furnish equal illumination. There are also other photometers, but those depending on the equality

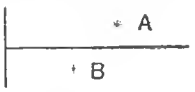

FIG. 1.

of illumination are by far the most extensively employed. The earliest photometer was devised by Bouguer and consisted of a vertical screen at right angles to a partition. On either side of the partition was placed a light so that it would illuminate one side of the screen. These lights were then adjusted until the two halves of the screen appeared of equal brightness. The distances of the lamps or lights from the screen were measured, and a proportion formed according to the law of the inverse squares. The screen, which was at first opaque, in later instruments was supplanted by one of ground glass, oiled paper, or other translucent material. An instrument based on the same principle which is in some respects modified is shown in the accompanying diagram (Fig. 2). Here A and B are the two illuminants,

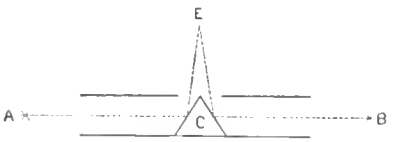

FIG. 2.

as before, and the rays of light fall on the surfaces of the prism C. The two lights are moved so that the surfaces of the prism appear equally illuminated to the eye of the observer at E. A simple and effective photometer was devised by Lambert in 1760, but as it was used extensively by Rumford some years later, it is known by his name. It consists of a vertical screen with a white surface, in front of which stands a cylindrical stick. The lights to be compared are placed in front of this stick, so that each will cast a shadow on the screen. These shadows represent the amount of light furnished by but one of the sources, consequently by varying the distances of the lights from the screen a position can be obtained where they furnish shadows of equal intensity. Measuring the distances of the lights from the screen, squaring the numbers, and forming a proportion, we can compare the intensity of the two illuminants. A second screen with an aperture cut in it may be placed parallel to the first with the lights in front of it

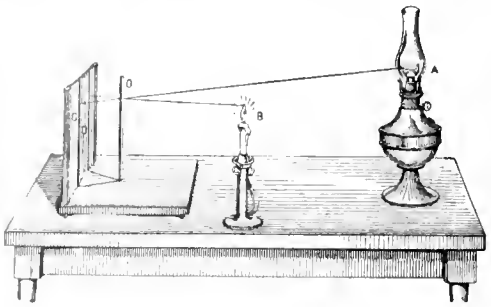

FIG. 3. RUMFORD PHOTOMETER.

and some little distance apart, so that each illuminates the screen by means of rays sent through the aperture. The two separate spots of light on the screen can be made equal by adjusting the lights and their comparative intensity computed as before. The photometer in most general use is that of Bunsen, where the two lights to be compared, A and B, are placed at the

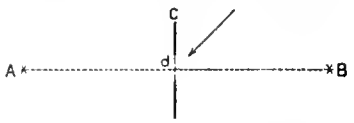

FIG. 4. BUNSEN PHOTOMETER.

opposite ends of the apparatus and a screen, C, whose face is perpendicular to the incident rays can be moved to and fro between them. This screen is made of a sheet of white paper with a central spot, *d*, produced by oil or grease, which appears bright on a dark ground by transmitted light, and dark on a light ground by reflected light. When the transmitted and reflected lights are equal in intensity the spot should disappear and the surface of the paper appear uniform, but in actual practice this condition is not realized. The sheet of paper is usually mounted in a box or carriage with mirrors or prisms enabling the observer to see simultaneously both sides of the paper, and is moved along a scale between the two lights, which is either graduated in units of length or indicates candle power direct. The reading is taken when the spot disappears as nearly as possible, and the candle power or relative intensity is determined as in the other cases. The arrangement of the lights, of course, varies in different forms of the instrument, as does also the construction of the box carrying the screen, but in general the results do not possess a greater accuracy than 4 or 5 per cent. The Rumford photometer cannot be depended upon closer than 8 or 10 per cent., but in all classes of photometric work much depends upon the observer.

The most modern and accurate photometer is that of Lummer and Brodhun, in which the central spot disappears entirely when the lights are of equal intensity. This is accomplished by the use of two right-angled prisms, one, E, with its hypothenusal face plane, the other, F, with this face ground spherical except in the centre, where a circular spot is perfectly plane. The two prisms are then placed with their hypothenusal sides adjacent, but separated except at the centre,

where the plane ground surface of the second prism is in contact with that of the other. The lights are placed at opposite ends of the apparatus, as in the case of the Bunsen photometer,

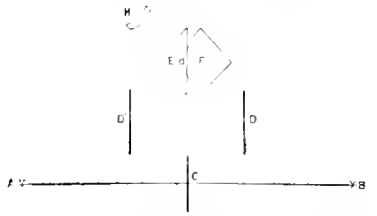

FIG. 5. PLAN OF LUMMER-BRODHUN PHOTOMETER.

and the rays fall on a central opaque screen, C, from which they are reflected to mirrors, D and D', and then to the faces of the prism. The rays from B entering the prism F, which has a spherical surface, undergo total reflection, except at the central portion (*d*), where the glasses are in contact. Therefore, only the rays passing through this central portion enter the second prism, E, and produce a spot of light of elliptical shape on its opposite surface. The rays from the other source of light, A, are reflected into the prism E, and by total reflection at the hypothenuse are brought to the third face of the prism, except those falling on the surface of contact, which enter the prism F. Consequently we have the surface of the prism E nearest the observer illuminated in part by the rays from one source of light and in part by rays from the other. If the illuminant to the left of the observer, for example, is of greater intensity, then we have a bright spot on a dark ground, and reversing the conditions the dark spot surrounded by light. When the lights are of equal intensity the spot entirely disappears and the field is uniform. The Lummer-Brodhun screen is usually mounted on a carriage which can be moved along a scale and which is easily reversed as a check on the observations. It also has a telescope, H, to observe the surface of the prism, which is a distinct advantage, as it permits the use of one eye and enables the observer to decide more accurately when the spot disappears.

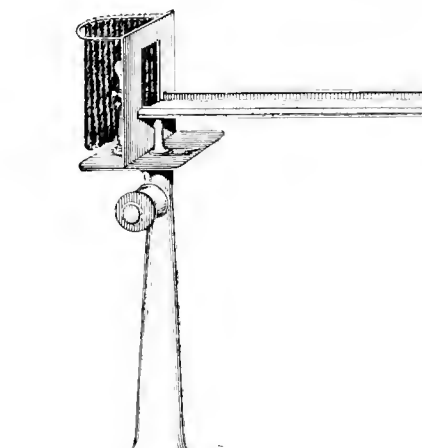

FIG. 6. LUMMER-BRODHUN PHOTOMETER.

The main difficulty in photometry is the comparison of lights of different colors, as then the determination of equally illuminated surfaces is an extremely difficult matter. For this purpose Rood, employing a principle first made use of by Whitman, has devised a 'flicker photometer' in which the light from two different sources is presented alternately to the eye in rapid succession. When the flicker disappears, it is shown that the light coming from one source is equal in intensity to that from the other.

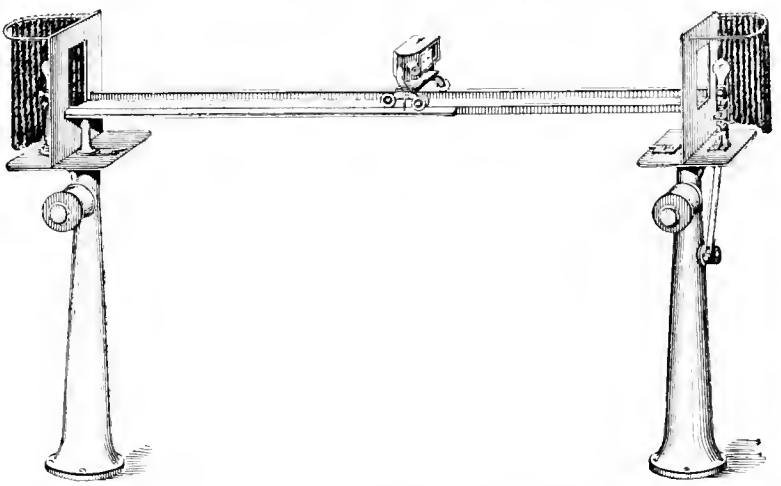

FIG. 7. LUMMER-BRODHUN PHOTOMETER ARRANGED FOR TESTING INCANDESCENT ELECTRIC LAMPS.

STANDARDS OF LIGHT. The question of standards of light possesses an intimate and important connection with photometry, and is a subject which is still attracting much attention from physicists. Until the International Congress on Electrical Units in 1883 adopted as the absolute standard the amount of light emitted by a square centimeter of melted platinum at the point of solidification, there was no really scientific unit in general use. Numerous forms of candles and lamps were employed, but little reliability could be placed on the results obtained in such tests and they did not form a satisfactory basis for subsequent or independent determinations. In France the standard used in photometric tests was the Carcel lamp, which burned purified rapeseed oil. The lamp was constructed according to certain fixed specifications, but it did not appeal to scientific men universally as an accurate standard. Candles have been used for a number of years as standards in spite of their many shortcomings; and we are now accustomed to have our electric and other lights rated in candle power. The candle in use in the United States

and England for photometric tests is the standard spermaceti candle, which burns 120 grains of material per hour and six of which weigh one pound. When this is prepared according to certain specifications as to size and form of wick, and burns with a flame 45 millimeters in height, the light emitted is considered unity. The stearin star candle was used in France and a somewhat similar candle in Germany, while a paraffin candle known as the *Vereinskerze* on account of its being adopted by the Union of German Gas Men was used in Germany and Austro-Hungary. The standard now commonly used in Germany is the acetate of amyl lamp of Hefner, which can be so adjusted as to be equivalent to the English candle. In practical photometry secondary standards consisting of incandescent lamps which have been standardized by comparison with some fundamental standard are used, and ordinary lamps are tested by reference to them.

Consult: Palaz, *Industrial Photometry*, translated by Patterson (New York, 1894); Stine, *Photometrical Measurements* (ib., 1900); *Record of the International Congress of Physicists, 1900* (Paris, 1901).

PHOTOPHONE (from Gk. *φῶς*, *phōs*, light + *φωνή*, *phōnē*, voice), RADIOPHONE, or SPECTROPHONE. Instruments in which radiant energy in the form of light acts to produce sound were devised by Prof. Alexander Graham Bell (q.v.) in conjunction with Sumner Tainter. The invention of the photophone arose from the employment of Willoughby Smith of selenium (q.v.) as a resistance medium in testing submarine cables. It was found that the electrical resistance of selenium varied considerably, and the discovery was made that this was due to the action of light, which lessened the resistance. Werner Siemens (in 1875) produced some extremely sensitive varieties of selenium, and in some of his experiments the resistance on exposure to light was found to be only one-fifteenth of what it was in the dark. Professor Bell substituted the telephone for the galvanometer and used intermittent flashes of light to produce a succession of changes in the conductivity of the selenium, corresponding in frequency to the musical vibrations within the limits of hearing, as it appeared to him that all the audible effects obtained from electricity could also be produced by variations in the light acting on selenium. He perceived the effect could be produced at the extreme distance at which selenium would respond to the action of a luminous body, and that this distance could be indefinitely increased by the use of a parallel beam of light, so that it would be possible to telephone from one place to another without a conducting wire, were apparatus devised by which variations could be produced in a parallel beam of light, corresponding to the variations in the air produced by the voice. After a number of experiments in which the resistance of the selenium cells was greatly reduced and other difficulties overcome, a form of photophone was devised in which light reflected from a plain mirror of flexible material, such as silvered mica or a microscope cover glass, against the back of which the speaker's voice is directed, was caused to vibrate with a frequency corresponding to that of the diaphragm itself. For reproducing sound at a distance sunlight or any other powerful light may be used, and a large beam is concentrated by means of a lens upon the diaphragm mirror, which after reflection is again rendered parallel by means of another lens. The beam is received at a distant station upon a parabolic reflector, in the focus of which is placed a sensitive selenium cell, connected in a local circuit with a battery and a telephone. The loudest effects were produced by rapidly interrupting the beam of light by a perforated rotating disk, revolving over the face of another perforated disk, with holes corresponding. These experiments led to others with substances other than selenium, and without the use of telephone or battery. A thin sheet of hard rubber was held close to the ear while a beam of intermittent light was thrown upon it by a lens, the result being the production of a musical note, and this effect was intensified by arranging the hard rubber as a diaphragm and listening through a hearing-tube. The conclusion was reached that sounds could be produced by the action of a variable light from substances of all kinds when in form of thin diaphragms. Subsequently Professor Bell concluded that sonorousness under the influence of intermittent light was a property of all matter. Various experiments with different fibrous and porous materials, such as cotton-wool, worsted, silks, sponge, lampblack, etc., indicated that lampblack may be substituted for selenium in an electrical receiver. In France, M. Mercadier passed an intermittent beam from an electric lamp through a prism and found a difference in the audible effects in different parts of the spectrum. These experiments were repeated by Professor Bell, who ascertained that sounds were obtained in every part of the visible spectrum excepting the extreme half of the violet, as well as in the ultra-red. A continuous increase in the loudness of the sound was observed upon moving the receiver gradually from the violet into the ultra-red, corresponding exactly with the proportion of heat in different parts of the spectrum, and showing that these effects are produced by the heat which accompanies light. Beyond this point the sound began to decrease, and then stopped so suddenly that a very slight motion of the receiver made all the difference between almost maximum sound and complete silence. Experiments with various substances led to the conclusion that the nature of the rays that produce sonorous effects in different substances depends upon the nature of the substances that are exposed to the beam, and that the sounds are in every case due to those rays of the spectrum that are absorbed by the body. These considerations led Professor Bell to construct a new instrument for use in spectrum analysis, which he termed a 'spectrophone.' The eyepiece of a spectroscope was removed and sensitive substances were placed in the focal point of the instrument behind an opaque diaphragm containing a slit. These substances are put in communication with the ear by means of a hearing-tube, and if we smoke the interior of our spectrophonic receiver and fill the cavity with peroxide of nitrogen gas, we have then a combination that gives us good sounds in all parts of the spectrum, visible and invisible, except the ultra-violet. Now pass a rapidly interrupted beam of light through some substance whose absorption spectrum is to be investigated, and bands of sound and silence are observed upon exploring the spectrum, the silent positions corresponding to the absorption bands. The ear cannot compete with the eye in the examination

of the visible part of the spectrum; but in the invisible part beyond the red the method is applicable. In working in this region of the spectrum, lampblack alone may be used in the spectrophonic receiver. Professor Bell stated that the spectrophone was only an adjunct to the spectroscope, but he considered that it would have a wide and independent field of usefulness in the investigation of absorption spectra in the ultra-red.

PHOTO-SCULPTURE. An ingenious use of photography to assist a sculptor in modeling portrait statues, or fac-similes and reduced reproductions of other statues, invented by M. Willème in 1867. The subject stands in the centre of a circular chamber, and is simultaneously photographed by no less than 24 cameras, arranged at equal distances round the chamber. The 24 photographs are subsequently made available in the sculptor's studio, where the clay model is arranged on a frame capable of being turned round. A magic lantern throws the outline of photograph No. 1 on a screen in front of the artist, who by means of a pantograph brings this outline to bear on the clay in its first position. The model is then turned round one twenty-fourth of a revolution, and the outline of photograph No. 2 is taken advantage of. Thus the modeler works his way in 24 changes round the model, and the likeness or fac-simile or reduced figure of the original is or should be complete. The method has been also applied to the taking of medallions and the like.

PHOTOSYNTAX (from Gk. *φῶς*, *phōs*, light + *σύνταξις*, *syntaxis*, arrangement). The first special term proposed (1893) to designate the process of the manufacture of carbohydrate food by green leaves under the influence of light. See PHOTOSYNTHESIS.

PHOTOSYNTHESIS (Neo-Lat., from Gk. *φῶς*, *phōs*, light + *σύνθεσις*, *synthesis*, combination). The process by which the green parts of plants construct carbohydrates under the influence of light. Carbohydrates are substances like sugars, starch, etc., which serve as the most important foods, both for plants and animals. The materials out of which the plant builds these foods are carbon dioxid and water. The idea current in the middle of the last century, and persisting even yet, that plants obtain their carbon compounds chiefly from the soil is erroneous. Few of the materials absorbed from the soil are fairly to be considered as foods. Carbon dioxid is present in normal air in minute quantities, usually less than three parts in 10,000. Yet it is absorbed by the aerial parts of plants, particularly the leaves, in sufficient quantities, because it finds its way by diffusion at high speed through the minute openings in the epidermis (stomata, q.v.) into the intercellular spaces which are bounded by moist cell walls. (See AËRATION.) In the water of these it readily dissolves and diffuses to the interior of the cells, where under proper illumination it is being used as rapidly as it can be absorbed. (See ABSORPTION.) It is not possible for the carbon dioxid to be dissolved in any considerable quantity by the superficial cells themselves, since the walls of these are more or less completely waterproofed to prevent evaporation. This effectually prevents solution and consequent diffusion of the carbon dioxide. The water necessary for food-making is obtained by absorption (q.v.) through the roots. The amount requisite for this purpose, however, is very small in comparison with the great quantities needed to replace that lost by evaporation. (See TRANSPIRATION.) Carbon dioxide does not merely dissolve in the water, but enters into loose chemical union with it, producing carbonic acid, which is highly unstable, as compared with the very stable carbon dioxide. Therefore it may be readily decomposed and its components rearranged to form a new substance. This is done by the living protoplasm.

The necessary energy is only obtainable when the plant is supplied with light of sufficient intensity. To obtain the requisite energy plants have developed in the cells lying near the surface minute protoplasmic bodies called chloroplasts, holding various green and yellowish pigments called collectively chlorophyll (q.v.). These pigments absorb only certain wave lengths of light, as shown in the accompanying absorption spectrum (Fig. 1). They derive their sole significance from their association with the living protoplasm, or enzymes (q.v.) produced by it. Like chemical action may be produced by protoplasm when energy is supplied to it in other ways, or when radiant energy of different wave lengths than that absorbed by chlorophyll is obtained. Thus certain bacteria containing purple pigments absorb some of the invisible ultra red rays, and these organisms are said to produce carbohydrates.

FIG. 1. THE ABSORPTION SPECTRUM OF CHLOROPHYLL.
The most important absorption bands are the three regions near the B, C, and D lines. The absorption to the right of the F line is faint and not easy to resolve into three bands. It seems to be due mainly to carotin.

It is possible to determine in some measure the influence of light waves of different lengths. It appears that the most efficient wave lengths are those which appear as red, orange, and yellow to our eyes. It has been clearly shown that absorbed light supplies the energy and that the chloroplasts do not act merely as a screen to cut off injurious or useless radiations, a theory which was once maintained with some vigor. The intensity of light adequate for photosynthesis approaches that of the brightest diffuse daylight. No plants are able in nature to secure sufficient carbon dioxide to utilize all the energy obtained from direct sunlight, though many of them are adapted to such conditions. Photosynthesis is nearly proportional to the intensity of the light, and though it is observable by proper methods in twilight, it has not yet been observed in so weak illumination as full moonlight. Artificial lights of various kinds are efficient in proportion to their intensity. Horticultural experiments in the United States and England have shown that electric light may be used for forcing certain plants in winter to a more vigorous development of foliage and vegetative organs. See ELECTRO-CULTURE OF PLANTS.

Scarcely any two cells of the plant receive the same amount of light. Those, therefore, which lie on the upper side and are first reached by the light are in the most favorable position for photosynthesis. As many as possible are developed by

leaves in [illegible] position. Indeed, the palisade region (see LEAF) depends for its mode of development on the action of light. The internal cells, receiving only that which has passed one or more external layers, work at a slower rate, although they are usually better situated for receiving an adequate supply of carbon dioxide. Window plants, receiving the light only from a very limited portion of the sky, at most 30 to 50 per cent., are usually more or less starved, because the energy received is inadequate in amount for the necessary food making. A comparison of the total energy received by the leaf and the amount stored in the carbohydrates formed shows that a relatively small amount of the kinetic energy has become potential in these compounds. Inability to determine the exact quantity of carbohydrate formed and to separate the energy absorbed by the chloroplasts from that absorbed by the other portions of the plant make such computations uncertain. From them, however, it appears that 1 per cent. or less of the total energy received by the leaf reappears in the starch of starch-producing leaves. The products of photosynthesis are probably unlike in different plants. Starch is often spoken of as the chief product of this process. It is probably not only a secondary product of photosynthesis, but it is certain that many plants do not form it at all. Most of the larger seaweeds, for example, make other carbohydrates and much of the carbohydrate food in the ordinary land plants is in the form of sugars, cellulose, gums, etc.

Practically nothing is certainly known of the details of the process of photosynthesis or of its first product. Several theories have been proposed; the most plausible is that of Baeyer, which has recently been receiving substantial support, although it is by no means yet clearly established. According to this theory the rearrangement of the elements of carbonic acid (H_2CO_3) results in the formation of formaldehyde (CH_2O) with the elimination of oxygen (O_2). After the production of formaldehyde it is condensed (or 'polymerized') into one of the simpler sugars, such as glucose ($C_6H_{12}O_6$), which could be formed by the proper union of six molecules of formaldehyde. This again could be polymerized to form cane sugar, and cane sugar has been shown to be one of the early products of photosynthesis in a number of ordinary leaves. Starch, which is a very complex carbohydrate, must result from further compounding, and therefore can be looked upon only as a still more remote product. Some of the supports for Baeyer's hypothesis are as follows: First, green leaves and even uninjured seedlings have been supplied directly with glucose, with the result that they nourish themselves therewith and store up reserve starch; second, it has been possible to supply one of the products intermediate between formaldehyde and glucose, namely glycerose ($C_3H_6O_3$), to starved plants in the absence of CO_2, with the result that they nourish themselves and store up starch; third, formaldehyde, though under ordinary conditions a violent poison, has been supplied at the moment of its formation to an alga and the plant nourished thereby; fourth, formaldehyde has recently been detected in the green leaves of active plants; fifth, formaldehyde is produced from CO_2 in light in liquid containing leaf-enzymes and chlorophyll, though no living protoplasm be present. Such experiments, while not conclusive, strongly support the idea that formaldehyde is the first product of photosynthesis.

The by-product of photosynthesis, oxygen, is nearly equal in volume to that of the carbon dioxide absorbed. On the average it is a little less, but in many experiments is at least 8 per cent. greater. In such cases the extra oxygen may be derived from the decomposition of other substances in the plant, since it is impossible to distinguish all sources of the evolved oxygen, which is always given off in the neutral (O_2).

It is not possible to ascertain exactly the amount of carbohydrates made under given conditions, since an indeterminate amount is used at once in the making of other more complex proteid foods, and still other indeterminate quantities are lost from any given region by migration. The net product has been determined in the sunflower as 1.6 to 1.8 grams of starch per hour per square meter; in the gourd, 1.5 to 1.7 grams; in the bramble, by a different method, 1.54 grams. The accumulation of the products of photosynthesis never reaches such a point in the normal plant that it interferes with the process. By artificial means, however, this result may be brought about. Since the supply of energy to a well-illuminated plant is more than sufficient to enable it to utilize all the carbon dioxide which can enter the cells under the usual small partial pressure of carbon dioxide, increasing the pressure of this in the atmosphere, and therefore supplying a greater quantity to the living cells, increases the amount of carbohydrates produced. This increase is almost proportional to the relative increase of CO_2, up to a point at which this gas retards other functions. An increase of CO_2 in the atmosphere from 3 parts in 10,000 to 600 or 800 parts proves beneficial for photosynthesis. Variations in other conditions, however, may so greatly affect this that inconsistent results may be obtained from experiments.

The rate of photosynthesis is affected by the temperature, increasing with a rising temperature to an optimum, which is not far from the optimum for growth. Yet it must be remembered that many plants flourish, and therefore may make food, at very low temperatures, e.g. the algæ in Arctic waters, or at very high temperatures, e.g. algæ in hot springs. In conifers, photosynthesis has been reported as occurring at temperatures even below 0° C. Though the leaves and surface tissues of plants are especially liable to lose water, and therefore to become flaccid, no interference with photosynthesis results.

PHOTOTAXIS (Neo-Lat., from Gk. *φῶς, phōs,* light + *τάξις, taxis,* arrangement, from *τάσσειν, tassein,* to arrange). (1) In animals, control of the direction of locomotion by light. Like the unicellular plants, the Protozoa as well as higher animals may migrate in a direction determined by that of the rays of light. According as the migration is toward or from the source of light, we can distinguish positive and negative phototaxis. The flagellate Infusoria (Chilomonas and Euglena) will move toward the light, crowding together on the illuminated side of the vessel. Amœba has been observed by Davenport to be strongly phototactic, showing that such responsiveness is a general property of protoplasm, the result of chemical changes produced by light. Ciliate infusorians are not markedly phototactic. Cells containing such different kinds of pigment

as the chlorophyll of plants and the retinal pigment of the eyes of arthropods respond to the action of light in a similar way, this response being an adaptive one. A striking example of phototaxis in pigmented cells (chromatophores) is described by Keller. He has discovered that the dark color of the (illuminated) skin is due to the rich branching at the base of the epidermis of black pigment cells lying deep in the cutis. In the dark, the pigment granules stream out of the branches into the cell-body, but the branches themselves are undisturbed. So long as the black pigment has this central position, the skin appears whitish. The light, on the contrary, causes the pigment, which is probably carried passively in the plasma, to move centrifugally. (See PIGMENT.) Hydra was observed by Trembley to wander toward the light, and this is of advantage to the animal because many of the Entomostraca on which it feeds are also phototactic. So also is the starfish. The phenomenon is especially marked in bilateral animals, such as planarians, annelids, crustaceans, flies and many other insects, mollusks, and vertebrates. As Davenport states, animals which live in shady places or in the dark are negatively phototactic, i.e. shun the light, while those living in the light are positively phototactic. The house-fly is well known to be phototactic, but its maggot shuns the light. Butterflies, says Davenport, are attuned to a high intensity of light, moths to a low intensity, so that bright sunlight, which calls forth the one, causes the other to retreat. On the other hand, a light like that of a candle, so weak as not to stimulate a butterfly, produces a marked response in the moth. The males and females of ants have been observed while mating in the air to be strongly phototactic, but after that period they show themselves neutral (Loeb). The larvæ (nauplii) of barnacles as well as other pelagic animals rise to the surface of the sea during the night, but descend before the strong sunlight. Temperature also affects phototaxis; a low temperature causes several of the normal responses, while under a high temperature it is accelerated; also Loeb has found that a concentrated medium, as when the water is rendered more salt, acts as the lower temperature. It is thought that, while in the retina of the eye the protoplasm is specialized for perceiving light, there is some evidence that in the eyeless animals the whole surface of the body contains such light-perceiving substances. This is well known to be the case with the earthworms, and perhaps with the oyster, Pholas, Unio, etc. The pelecypod Psammobia, the blind Proteus of caves, and Triton cristatus when blinded, are irritated by rays of light, especially the blue rays, falling on the skin. Consult Davenport, *Experimental Morphology*, part i. (New York, 1897), which contains a full bibliography. Compare TROPISM.

(2) In plants, the sensitiveness to illumination. This may be fundamentally the same as heliotropism (q.v.). The effect of light upon the organism may be to accelerate or retard the movements of the motor organs on the illuminated side, this causing the body to be rotated until both sides are equally illuminated (see CHEMOTAXIS and CHEMOTROPISM), when any progress will then necessarily be toward or away from the source of light. Organisms which approach the source of light are said to be positively phototactic, those which recede from it negatively so. The same organism may show successively both forms of response in light of different intensity. For instance, Euglena viridis is positively phototactic in weak light, but negatively so in strong.

PHOTOTHERAPY (from Gk. *φῶς, phōs*, light + *θεραπεία, therapeia*, cure, from *θεραπεύειν, therapeuein*, to cure, from *θεράπων, therapōn*, attendant). Treatment of disease by means of light. The method of applying light for therapeutic purposes, devised by Dr. Niels R. Finsen, of Copenhagen, about 1896, is founded on the following data: (1) The bactericidal property of the chemical rays of light; (2) the power of the chemical rays of light to produce an inflammation of the skin (sunburn, *erythema solare*); (3) the power of the chemical rays of light to penetrate the skin. The violet and ultra-violet rays of light obtained from the sun or from an electric arc-lamp will, in a few hours, kill plate cultures of Bacillus prodigiosus at a great distance. The so-called sunburn is not a burn. If sunlight or electric light be passed through a layer of distilled water so arranged as to cut out the ultra-red rays (the dark rays of heat), the resulting skin-inflammation is as great as if the light were uncontrolled. If sunlight be thrown upon the skin through a glass screen which cuts out the violet and ultra-violet rays, there is no resulting inflammation. Again, if small sealed bottles containing muriate of silver be placed under the skin of some animals kept in the dark, and of some animals exposed to the sun, if the tubes be removed an hour later, it will be found that the muriate of silver is blackened in the cases of the animals which were exposed to the sunlight, but not in the cases of those kept in the dark. It is shown by experiment that the chemical rays of light penetrate more easily in bloodless tissues than in those filled with blood. In a piece of sensitized paper put against the back of a man's ear upon the front of which the blue and violet rays are allowed to fall for 5 minutes, no reaction takes place. If the paper be replaced and the ear be compressed tightly between two glass plates and exposed again to the same light, the paper will be blackened after 20 seconds' exposure. In the treatment of patients, sunlight is used in the summer, when the sky is bright, but otherwise the light of electric arc-lamps of 50 to 80 amperes is employed. Concentration of the light is necessary to render it powerful as a bactericide. To avoid burning the skin, the light must be colored. To make the sunlight strong and cool Finsen devised a special apparatus, consisting of a lens about 20 to 40 centimeters in diameter. The lens, composed of a plain glass and a curved one, is framed in a brass ring, with a bright blue, weak ammoniacal solution of sulphate of copper between them. The water absorbs the ultra-red rays and, being blue, it excludes much of the red and yellow rays. The excluded heat rays have little bactericidal power; whereas the blue, violet, and ultra-violet rays are but slightly impaired in chemical or bactericidal power. The lens is so hung that it can be raised and lowered as well as turned on a vertical and horizontal axis, by which means it can be placed perpendicularly to the sun's rays, and at such a distance as to make the light strike the diseased area. For concentrating the electric arc-light Finsen devised an

apparatus consisting of lenses of quartz framed in two brass tubes, telescoping the one within the other. Quartz allows the ultra violet rays (even those of very short wave-length) to pass through it much more easily than through glass, and these rays from the electric light are of less length than those from sunlight. Facing the lamp are placed two lenses having together a focal distance of 12 centimeters. At this distance from the lamp, those lenses will concentrate and render parallel the divergent rays from the lamp, and direct them through the brass tubes, at whose distal end they strike two quartz lenses. These lenses concentrate the parallel rays and converge them till they are united about 10 centimeters beyond the outer lens. The space between these latter lenses is filled with distilled water which absorbs the ultra-red rays, but does not impair the blue, violet, and ultra-violet rays. Surrounding this end of the apparatus is a mantle, through which cold water flows to prevent boiling of the distilled water between the lenses. In spite of all this precaution, the light is still too warm, and the skin must be cooled to avoid burning. This is effected by an apparatus consisting of a plate of quartz and a plain convex lens of quartz, both fitted into a conical brass ring, which carries two small tubes and four arms. To each arm is fastened an elastic band by means of which the apparatus is pressed against the skin. Cold water is run into one tube and out of the other, and thus the skin is cooled so that it can tolerate the strongest light. The pressure of the plano-convex lens on the skin renders it anæmic, thus fitting it for the easy penetration of the chemical rays. A small area of the skin is treated for an hour each day. The skin swells and becomes red, and a bulla may appear; but sloughing has not resulted. During the application the nurses are obliged to wear dark glasses to protect their eyes from the brilliant light. Dilatation of cutaneous vessels by the violet rays may continue for six months. Many diseases of supposed bacterial origin have been treated by this method, but cures have resulted only in cases of *lupus vulgaris, lupus erythematosus, alopecia areata, and carcinoma.* The greatest success has been reached in cases where there was an absence of scarring, of pigmentation, of great vascularity, of great depth below the surface, of involvement of eyelid or mucous membranes, or of great extent of lesion.

The number of patients at Finsen's Institute has increased from seven in 1897 to an unnumbered clientèle, with over a hundred on a waiting list. A Brooklyn, N. Y., physician has opened an institute for Finsen's treatment. The Roentgen or X rays (q.v.) penetrate to deep layers not reached by sunlight or electric light. Consult Morris & Dore, "Finsen's Light Treatment of Lupus and Rodent Ulcer," in *British Medical Journal*, February 9, 1901.

PHOTOTROPISM (from Gk. *φῶς, phōs*, light + *τροπή, tropē*, a turning, from *τρέπειν, trepein*, to turn). A sensitiveness of plant organs to light, by virtue of which they bend to assume definite positions with reference to the direction of light incident upon them. See HELIOTROPISM.

PHRANZA, frän'zä, or **PHRANZES**, frän'zēs (Gk. *Φραντζῆ, Phrantzē*). George (1401-78). A Byzantine historian, born at Constantinople. He was secretary to the Emperor, Manuel II., and held other high offices, but at the fall of Constantinople was obliged to flee, and ended his days in an Italian monastery, where he wrote his valuable *Chronicle*, embracing the period of Byzantine history from 1259 to 1477. It was printed in Vienna in 1796, and translated into Latin in 1838.

PHRASE (Lat. *phrasis*, from Gk. *φράσις*, manner of speech, from *φράζειν, phrazein*, to declare). The name given, in music, to the simple motives containing in themselves no satisfactory musical idea, which enter into the composition of every melody containing a perfect musical idea, e.g.

The phrase most usually consists of two measures; in compound time it may be comprised in one measure, and an extended phrase is one which contains three measures. In the more simple and regular forms of musical composition, two phrases unite to form a section, ending in a cadence, and a perfect musical idea is formed of two such sections terminating, the first with the dominant, the second with the tonic harmony. See FORM.

PHRASING. The proper rendering of musical phrases. (See PHRASE.) A musical composition is analogous to a literary one, the sentences being replaced by phrases; upon their correct interpretation depends the intelligible presentation of the whole piece. One of the most important elements of phrasing is accent (q.v.), the general principles of which will be found under RHYTHM; but in no case must an accent be so insisted upon as to break the unity of the musical phrase. On the contrary, the ordinary accent is often postponed or anticipated in order to emphasize the general effect of the phrase. For the same reason, especially in rapid passages, accents are often added; while in quick movements accents are sometimes omitted so as to give an impression of unity to a number of separate bars. Two common faults in phrasing are breaking up a group of notes which together form a musical sentence, and running together two distinct sentences. In instrumental work, especially, there is a tendency to make a break at the end of a bar; but in reality a sentence always ends on the accented division of a bar, the bar-stroke having absolutely no relation to phrasing. In vocal music the musical accents correspond with those of the text, and the phrases are, as a rule, dependent upon the lines or word sentences. Vocal phrasing, therefore, is obviously much simpler than instrumental. The signs most commonly used to indicate phrasing are the dash; the curved line, denoting *legato;* and the slur; but the interpretation of any composition is to a great extent a matter of personal appreciation and discrimination. For some helpful suggestions on the subject, consult: Ehrenfechter, *Delivery in the Art of Pianoforte Playing* (London, 1897); Goodrich, *Theory of Interpretation* (Philadelphia, 1899); Lussy, *Traité de l'expression musicale* (6th ed., Paris, 1892).

PHRENOL'OGY (from Gk. *φρήν, phrēn*, heart, mind + *-λογία, logia*, account, from *λέγειν, legein*, to say). The theory that the mind consists of a number of independent faculties, each of which has a definite localization in a region

of the brain whose size is indicative of the degree of the faculty resident in it. Franz Joseph Gall (q.v.), an eccentric Viennese physician, announced about 1796 the discovery of a system of phrenology. He asserted that he had arrived at his results empirically, having for several years examined the heads of individuals who exhibited unusual mental or moral endowments. By these examinations he made out a system of correlations between the topography of the skull and the traits. He further concluded that the size and configuration of the brain was indicated by the size and configuration of the skull. His lectures, begun in 1796, ceased at the order of the Austrian Government in 1802, his doctrines being judged to be materialistic and inimical to the truths of morality and religion. In 1804 he associated with him his favorite pupil, Johann Gaspar Spurzheim (q.v.), and the two traveled through Germany, Prussia, and Switzerland to France. In Paris, the French Institute appointed a commission to investigate their assertions. This commission reported favorably upon certain methods of dissection, etc., but regarded their main conclusions as hypothetical. In 1809 the two began publishing a large work, *The Anatomy and Physiology of the Nervous System in General, and of the Brain in Particular, with Observations upon the Possibility of Ascertaining Several Intellectual and Moral Dispositions of Man and Animals by the Configuration of Their Heads*. Gall died in Paris in 1828, and was interred with the greatest marks of respect and honor. Spurzheim came to America in 1832, but died suddenly shortly after his arrival at Boston.

The fundamental tenets of phrenology are that the brain is the material substratum of mind, that it is a multiplex structure, composed of a definite number (originally 34, now 42) of constituent organs, each of which is the seat of a particular power of the mind—a 'sentiment,' a 'propensity,' or an 'intellectual faculty.' Furthermore, phrenology teaches that these 42 organs, or pairs of organs, constitute a series of cones with their apices at the oblongata and their bases at the surface. Each prominence in the skull indicates the size of the organ just beneath it, and in that way the development of the correlated mental faculty; for this development varies directly with the volume of its brain substrate, and, conversely, the exercise of any faculty promotes the growth of its brain seat. The 'propensities' or 'passions,' situated at the lower and posterior part of the brain, are amativeness, philoprogenitiveness, continuity, adhesiveness or friendship, combativeness, destructiveness, constructiveness, acquisitiveness, secretiveness, inhabitiveness, alimentiveness, vitativeness, and conjugal love. The 'sentiments,' situated at the superior portion of the cranium, are self-esteem, love of approbation, cautiousness, firmness, benevolence, veneration, hope, ideality, conscientiousness, spirituality, and sublimity. The 'intellectual faculties,' in the anterior region, are individuality, form, space or size, weight or resistance, color, locality, order, duration, number, tune, language, comparison, causality, wit, imitation, supernaturality or wonder, human nature, and suavity. In actual diagnosis, the size of the prominence determined the degree of the faculty only when taken in conjunction with other tendencies, for one faculty might aid or inhibit the function of another.

It is scarcely necessary to say that, as a pretension to a science, phrenology is related to modern neurology as astrology to astronomy, or alchemy to chemistry. It did, indeed, serve a useful purpose in stimulating the investigation of cortical function, in instilling the principle of the dependence of consciousness upon the cerebrum, and in offsetting the extreme views of men like Magendie and Flourens, who believed that the brain functioned homogeneously like the lungs or the liver. But in the light of modern knowledge phrenology is bad psychology and bad neurology. Modern psychology does not regard the mind as a bundle of faculties. Its components are determined rather by the contributions of the various sense-organs to its structure than by the types of activity by which the psychological self seems to acquire knowledge or express its attitude. Neurologically, too, there are many disproofs of phrenology. Different skulls have a different thickness; the same skull varies in thickness in different regions; prominences on the surface do not necessarily indicate a greater size in the part of the brain beneath; there is no correlation between brain weight and intelligence; three-fifths of the gray matter of the cortex is concealed in the sulci; loss of portions of the brain by accident or disease destroys or impairs the sensory or motor functions connected with some sense department, or some association system, not some 'faculty.' Finally, the whole structure of phrenology falls with the modern investigations of cortical localization by the methods of degeneration, electrical stimulation, medullation, and extirpation. See PHYSIOLOGY.

PHRIXUS (Lat., from Gk. Φρίξος). The son of Athamas and Nephele. With his sister Helle he was rescued by his mother when about to be sacrificed to Zeus, and carried to Colchis upon a ram with golden fleece. On the journey Helle fell into the waters called after her, the Hellespont. The fleece of the ram, given to King Aëtes and hung upon the grove of Ares, was the object of the Argonautic Expedition.

PHRYGIA, frij'i-ä (Lat., from Gk. Φρυγία). A country in Asia Minor, the extent and boundaries of which varied very much at different periods of ancient history. Originally, the boundaries toward the east were the river Halys and the territory about Iconium, which was the last Phrygian city; toward the south, it touched the Taurus and the Pisidian Mountains; on the north, it reached the Hellespont and Propontis; on the west, it seems to have included the Troas and Mysia, and may have held suzerainty over Lydia and Caria. Later invaders from Thrace, who occupied Bithynia and Mysia, cut this region into two parts: Little Phrygia, a somewhat indefinite region south of the Hellespont, and Greater Phrygia, which alone preserved the national character. This was bounded on the north by Bithynia and Paphlagonia, on the east by Pisidia Lycaonia, on the south by Cappadocia, and on

the west by the maritime countries of Mysia, Lydia, and Caria. The boundaries were further modified by the Gallic invasion of the third century B.C. (See GALATIA.) Pergamene conquests added part of Southern Bithynia, including the important city of Dorylæum, under the name of Phrygia Epictetus. The Roman provincial administration divided Phrygia, attaching the northeastern part to the Province of Galatia and the western portion to the Province of Asia. Phrygia was in general a high and somewhat barren plateau, though its pastures supported immense flocks of sheep, noted for the fineness of their wool, as indeed they still are. The most fertile part was the valley of the Sangarius, but the most beautiful and populous district was the southwestern, at the base of the Taurus, where the Mæander and other streams had their rise, and here were the chief cities, Synnada, Celænæ, Apamæa, Colossæ, Laodicea, while farther to the east was Antioch. The mountains and streams yielded gold; Phrygian marble was anciently celebrated, and the cultivation of the vine appears to have been extensively carried on.

The Phrygians were certainly an Indo-European race, and seem to have entered Asia Minor from Thrace, pushing into the interior from the Troad along the valley of the Sangarius, and making themselves masters of the whole tableland, and probably extending their sway over the Asiatic tribes on the coast. We hear of a race of powerful kings alternately bearing the name of Gordius and Midas, and in the mountains near the headwaters of the Sangarius are the great rock-cut tombs or façades which were associated with these rulers. The invasions of the Cimmerians (c.675 B.C.) seem to have broken their power, and henceforth they played no part in history, but fell first under the rule of the growing Lydian kingdom, then under Persia, Macedon, Pergamum, and Rome. They seem to have been a peaceful rustic people, devoted to agriculture and cattle raising. Their religion was an ecstatic nature worship in which the Great Mother of the Gods, Rhea or Cybele, and a male deity, Sabazius, played a great part. The orgiastic rites and wild music seem to have exercised considerable influence upon the Greeks and Romans, and we find their deities transplanted to the Western world. Consult: Ramsay, *Historical Geography of Asia Minor* (London, 1890), and especially his incomplete work, *Cities and Bishopries of Phrygia* (Oxford, 1895-97).

PHRYGIAN CAP. See LIBERTY CAP.

PHRYGIAN LANGUAGE. The native language of the Phrygians is known partly through glosses preserved by Hesychius and other lexicographers and authors, partly through inscriptions found in the territory once occupied by this people. Tombs with inscriptions were discovered in the valley of Doghanla by Colonel Leake in 1820. Four of these inscriptions, including that on the sepulchre of King Midas, were first published by Hamilton in 1842. A number of additional inscriptions were published by Ramsay in 1883 and others copied by himself and Sterrett appeared subsequently. Many of these are in Greek, but have Phrygian additions at the end. That the additions contain formulas of execration was first surmised by Schmidt in 1869. The researches of Ramsay and Fick have corroborated this conjecture. As Herodotus (vii., 73) and Strabo (xlvii., cexcv.) declare that the Phrygians were related to the Armenians and the Thracians, it was natural that the language should be supposed to be Armenian. That was done by Mordtmann and Gosche. A collection of 63 glosses was made by Lagarde. He concluded that the Phrygians were derived from the Thracians and that their Iranian character was proved by such words as *ἀδάμνα* and *κύρβαντ*. There seems to be good reason for assuming that the Phrygian language belonged to the Iranian family. While most of the monuments found belong to the Roman period, there are some that have plausibly been assigned by Ramsay to the end of the eighth century B.C. If one doubtful letter is a χ rather than a ψ, as seems probable, the Phrygians apparently received their alphabet, not from the Ionians, but from the old Æolians. After the Phrygian language had been supplanted by the Greek, it still maintained itself in imprecations, believed to be more efficacious in the speech of the fathers. The same alphabet has been found at Abu-Simbel in Egypt in inscriptions that must date from B.C. 650-590 and in an inscription found in Lemnos in 1886 in an unknown language and of uncertain age. Consult: Leake, *Journal of a Tour in Asia Minor* (London, 1824); Hamilton, *Researches in Asia Minor, Pontus, and Armenia* (ib., 1842); Stewart, *Ancient Monuments of Lydia and Phrygia* (ib., 1842); Lagarde, *Gesammelte Abhandlungen* (Leipzig, 1866); *Corpus Inscriptionum Græcarum*, iii. 3810, et seq.; Schmidt, *Neue lykische Studien* (Jena, 1869); Fick, "Zum Phrygischen," in Bezzenberger's *Beiträge*, xiv., 50; Ramsay, in *Journal of the Royal Asiatic Society*, xv. (London, 1883); id., in *Journal of Hellenic Studies* (London, 1882, 1884); id., in *Zeitschrift für vergleichende Sprachforschung*, xxviii. (Gütersloh, 1887).

PHRY'NE (Lat., from Gk. *Φρύνη*). One of the most celebrated courtesans of antiquity. She was a daughter of Epicles, and was born at Thespiæ, in Bœotia. She was of very humble origin, and is said originally to have gained her livelihood by gathering capers, but her beauty afterwards brought her such wealth that, when Alexander destroyed the walls of Thebes, she is said to have offered to rebuild them, if she might be allowed to inscribe on them the words: "Alexander destroyed them, but Phryne, the courtesan, rebuilt them." Being on one occasion accused by Euthias of profanation of the Eleusinian mysteries, she was summoned before the court of the Heliasts and was there defended by the orator Hyperides; but Hyperides, seeing that the verdict of the court was likely to be an unfavorable one, threw aside her veil and exposed her bosom and shoulders: the judges thereupon acquitted her, and she was carried in triumph to the Temple of Aphrodite. She served as the model for Praxiteles's Cnidian Venus, and for the Anadyomene (q.v.) of Apelles, she having, on the occasion of a festival at Eleusis, entered the sea, unclad, in the presence of the assembled throng. Her neighbors dedicated to her at Delphi a gilded statue resting on a base of Pentelic marble, the whole the work of Praxiteles. There is preserved in Athenæus an epigram in her praise written by Praxiteles and inscribed on a statue of Cupid, which he presented to her and which she dedicated at Thespiæ.

PHRYNICHUS, frĭn'ĭ-kŭs (Lat., from Gk. *Φρύνιχος*). A Greek tragic poet of Athens, an older contemporary of Æschylus. He won his first victory in B.C. 511 and his last in 476, when Themistocles was his *choragos*. Like Æschylus, he is said to have died in Sicily. In all the accounts of the rise and development of the tragedy, Phrynichus is ranked immediately after Thespis, and according to some critics he should be regarded as the real inventor of tragedy. He was the first to bring female characters on the stage; for the light satyr plays of his predecessors, he substituted plays on serious subjects taken both from the heroic age and from the history of his own time; and he was the first to introduce an actor distinct from the leader of the chorus, and thus to open the way for the development of the dialogue. In his works, however, the lyrical choruses still retained the principal place, and these are said to have been so celebrated that they were sung even in the time of Aristophanes. Of his plays, the most important were *Φοινίσσαι*, which dealt with the defeat of the Persian invaders (B.C. 480), and is said to have been copied by Æschylus in *The Persians*, and *Μιλήτου ἅλωσις*, on the capture of Miletus by the Persians. According to Herodotus, the Athenians were so moved by the latter tragedy that they fined the poet one thousand drachmas for recalling to them the disasters of their kinsmen, and passed a law forbidding further performances of the piece. Only a few fragments and the titles of nine of his plays are extant. Consult: Nauck, *Tragicorum Græcorum Fragmenta* (Leipzig, 1856).

PHTHIOTIS, thī-ō'tĭs (Lat., from Gk. *Φθιῶτις*). In ancient geography, the southern part of Thessaly, north of Ænis and Malis, and west of the Pagasæan Gulf. The district was famous in the epic as the home of Achilles, and from this region the Æolian colonization of Asia Minor seems to have gone forth. The population, though maintaining a Thessalian element, was considered to be Achæan. The chief cities were Phthiotian Thebes, Larisa, Lamia, Melitæa, and Thaumaci.

PHTHISIS, thī'sĭs. See TUBERCULOSIS.

PHY'COCY'ANIN (from Gk. *φῦκος, phykos*, seaweed + *κυανός, kyanos*, blue). The peculiar pigment, usually bluish-green, of the blue-green algæ. See CYANOPHYCEÆ.

PHYCOERYTHRIN, fī'kō-ĕr'ĭ-thrĭn (from Gk. *φῦκος, phykos*, seaweed + *ἐρυθρός, erythros*, red). The red pigment of the red algæ contained in the chromoplasts, and giving the general tint of the plant body. See RHODOPHYCEÆ.

PHYCOMYCETES, fī'kō-mī-sē'tēz (Neo-Lat. nom. pl., from Gk. *φῦκος, phykos*, seaweed + *μύκης, mykēs*, fungus). A group of plants which comprises, as the name indicates, those fungi most resembling the algæ. (See FUNGI.) The Phycomycetes include the black molds (Mucorales), certain insect parasites (Entomophthorales), the water molds (Saprolegniales), and a group of very important plant parasites included in the order Peronosporales. The simplest of the Phycomycetes are unicellular aquatic forms (Chytridiales) that generally live parasitically in the cells of algæ. These representatives are usually observed in a quiescent condition, in the form of thick-walled spores or resting spore-cases, but there are motile periods in the life history when the organisms swim freely in the water. The Entomophthorales are mostly

WHITE MILDEW (*Albugo Candida*).

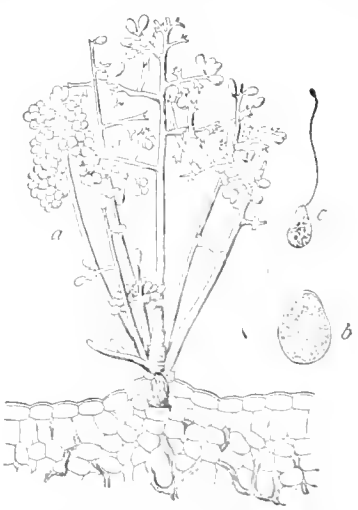
parasitic on insects, preferring the Diptera and Orthoptera, a common representative (Empusa) being found on the house fly. Late in the summer and in the autumn dead house flies may



GRAPE MILDEW (*Plasmopara*).

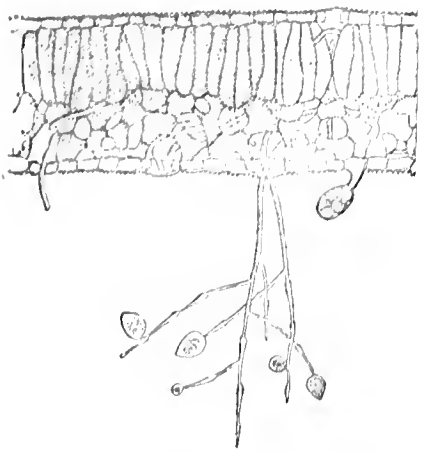
frequently be observed attached by their proboscæs to window panes, walls, and other sur-

tree, with [illegible] of yellowish powder on the surface around them. This powder is made up [illegible] pore. That have been thrown off from the ends of tubular filaments, which after filling the body of the insect have grown through the segment to the exterior. The large common molds (Mucorales) are frequently called black molds because of the color of the spore cases (sporangia), and to distinguish them from the green and yellow mildews. They are saprophytes, growing upon organic matter in damp places, the bread mold (Mucor) being a familiar example. The vegetative portion of the molds (mycelium) consists of conspicuous threads (hyphæ) plainly visible to the eye, which grow over the sub-



DOWNY MILDEW OF POTATOES (*Phytophthora infestans*). Cross section of leaf showing growth of mildew.

stratum and when possible penetrate it in all directions. The commonest fructification is a black, swollen head (sporangium) containing thousands of spores, and borne at the end of an erect branch (sporangiophore). The Peronosporales are an assemblage of forms, mostly parasitic, and contain some fungi responsible for such serious diseases as the rot of potato and the downy mildews of grapes. (See paragraph *Diseases* under GRAPE and POTATO.) Another troublesome form, sometimes placed among the Peronosporales and sometimes among the Saprolegniales, is Pythium, the fungus responsible for the 'damping off' (q.v.) of seedlings. The water molds (Saprolegniales) have habits widely different from other Phycomycetes, being aquatic and living on dead insects, fish, and frogs, and sometimes on the living animals. They surround the body with a beautiful halo of delicate radiating filaments. These fungi sometimes cause epidemics in fish hatcheries, where they attack the mouths and gills of young trout and salmon. Consult Lindner and Pranti, *Die natürlichen Pflanzenfamilien* (Leipzig, 1887–).

PHYCOPHÆIN (from Gk., *φῦκος, phukos*, seaweed + *φαιός, phaios*, dusky). The brown pigment characteristically present in the cells of the brown algæ. See PHYCOPHYCEÆ.

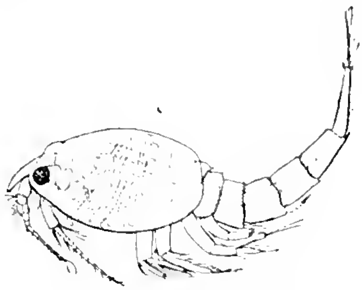
PHYLACTERY (Lat. *phylacterium*, from Gk. *φυλακτήριον, phylakterion*, safeguard, amulet, from *φυλακτήρ, phylaktēr*, sentinel, guard, from *φυλάσσειν, phylassein*, to guard). An amulet or charm worn as a protection against evil influences. In the New Testament the name is given to a strip of fine parchment inscribed with certain passages from the Scripture (Exod. xiii., 1-10; xiii., 11-16; Deut. vi. 4-9; xi., 18-21), and inclosed in a small leathern case. This was, in accordance with a literal interpretation of Exod. xiii. 9-16; Deut. vi. 8, 9, 18, fastened by leathern straps to the forehead, just above and between the eyes, or to the left arm, at the point where the arm, hanging down, falls nearest the heart, or sometimes to the door-post.

PHY'LÆ (Lat. nom. pl., from Gk. *φυλή, phylē*, tribe). In Greek political institutions, the tribes or clans, originally perhaps embracing all the inhabitants of a district, though in many cases there seems to have been a theory of common descent rather than residence. Among the Dorians we regularly find the three tribes, Hylleis, Dymanes, and Pamphyli; at Miletus in Ionia and at Athens we find Geleontes, Argadeis, Ægicoreis, and Hopletes, and these names recur in other Ionian communities. The most important development of the tribe was in the reorganization of the Athenian democracy by Clisthenes after the expulsion of the tyrant Hippias (B.C. 510). The four old tribes were swept away, and the whole people divided into ten tribes on the basis of the demes, in which the people were registered. The demes in each tribe were so selected that the three divisions, Mountain, Coast, and Plain, were all represented. The tribes, which were named from heroes, were Erechtheis, Ægeis, Pandionis, Leontis, Acamantis, Oeneis, Cecropis, Hippothontis, Æantis, Antiochis. The tribes were organized as corporations, and held regularly meetings, apparently at Athens, but not in their own halls. The executive officers were the Epimeletæ, and a treasurer who had charge of the property of the tribes, for as each eponymous hero had priest and sanctuary, and received a certain part of all booty in war, the tribe had to manage certain lands and investments. The tribe chose its representatives on State commissions where work was divided among the tribes, such as the repair of walls, etc. They also elected the rich men whose duty it was to provide the choruses for intertribal competition at the festivals, or other similar public duties laid upon the rich. The military organization was based on the tribal division, for each tribe furnished a regiment of infantry under a taxiarch and a squadron of cavalry under a phylarch. Though the Senate was composed of fifty from each tribe, the senators were not chosen by the tribe but by the demes, among whom they were apportioned on the basis of population.

PHYLARCHUS, fi-lär'kŭs (Lat., from Gk. *Φύλαρχος*) (*c.*210 B.C.-?). A Greek historian. He was born probably at Naucratis, in Egypt, but spent most of his life at Athens. His great work was a history of Greece, embracing the fifty-two years between the invasion of the Peloponnesus by Pyrrhus (B.C. 272) and the death of Cleomenes III., King of Sparta (B.C. 221). His style was graphic and animated, but according to Polybius (ii., 56) he frequently falsified history on account of his passionate admiration for Cleomenes. The work was used by Trogus Pompeius and by Plutarch in his lives of Cleomenes and Aratus. The few extant fragments have been edited in Müller's *Fragmenta Historicorum Græcorum* (Paris, 1868).

PHYL'LIS (Lat., from Gk. Φυλλίς). (1) A Thracian princess, betrothed to Demophoön, the son of Theseus, who left her to go to Athens, promising to return at a certain date. When the appointed time had passed without his arrival, Phyllis killed herself and was changed into an almond tree, which put forth leaves only when Demophoön shortly afterwards returned and embraced it. (2) In pastoral poetry, a name conventionally used of a maiden or lady-love.

PHYLLOCAR'IDA (Neo-Lat., from Gk. φύλλον, *phyllon*, leaf + καρίς, *karis*, shrimp). A highly composite or generalized order of Crustacea, separated by Packard from the Phyllopoda. The group is represented at the present time by Nebalia and its allies (Nebaliidæ) of the North Atlantic, forming the Leptostraca of Claus; also by fossil forms from the Cambrian period to the end of the Carboniferous, some of which were over a foot in length, while Nebalia itself is about half an inch long. In Nebalia the



A PHYLLOCARID (*Nebalia bipes*).

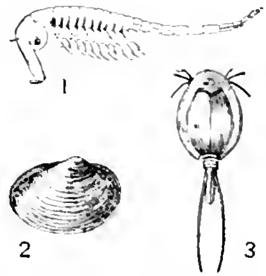
body is compressed and protected in front by a bivalved carapace, closed by a weak adductor muscle, but without a hinge; the rostrum is free, movable; the eyes stalked; the eight pairs of thoracic legs resemble those of phyllopod crustacea, and the hind body is modeled on that of a copepod crustacean such as Cyclops. It undergoes no metamorphosis, and is an example of the persistence of type from very early geological times.

PHYL'LOCLAD (from Gk. φύλλον, *phyllon*, leaf + κλάδος, *klados*, branch), or CLADOPHYLL. A branch that functions as a leaf, which it resembles in form and color. Well known illustrations are the 'leaves' of smilax and asparagus.

PHYL'LODES (from Gk. φυλλώδης, *phyllōdēs*, leaf-like). Leaf petioles which have developed as blade-like organs that replace regular blades. They occur only among dicotyledons. Phyllodes may be distinguished from true leaves by the parallel veining, and also by presenting their edges up and down (profile position). The greatest display of phyllodes is found among the acacias of Australia, where nine-tenths of the numerous species have phyllodes instead of true leaves. The normal blade of these acacias is pinnately compound, as is shown by their seedlings, and occasionally when older growths are subjected to unusual conditions. In the case of pitcher plants (see CARNIVOROUS PLANTS) the urns, tubes, etc., are usually regarded as hollow phyllodes, the true blade being represented by the more or less conspicuous lids.

PHYL'LOGRAP'TUS (Neo-Lat., from Gk. φύλλον, *phyllon*, leaf + γραπτός, *graptos*, written, from γράφειν, *graphein*, to write). A genus of fossil graptolites, index fossils of the Lower Ordovician rocks of North America and Northern Europe. The thecæ, or cells in which the animals lived, are arranged in four rows with their dorsal sides united along a common axis to form a four-bladed colony, the blades of which are at right angles to each other. See GRAPTOLITE.

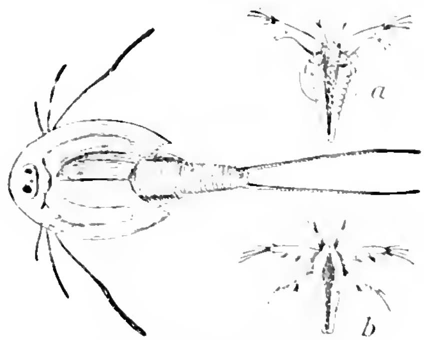
PHYLLOP'ODA (Neo-Lat. nom. pl., from Gk. φύλλον, *phyllon*, leaf + πούς, *pous*, foot). An order of fresh-water Crustacea, in which the legs are broad and leaf-like, subdivided into lobes, and adapted for respiration as well as locomotion. The trunk is not differentiated into a thorax and abdomen. The eyes are usually simple or compound, and either sessile (Apus) or stalked (Branchipus), while there is a median



PHYLLOPOD CRUSTACEANS.

1. *Branchinectis Coloradensis*; 2. Shell of *Estheria Belfragei*; 3. *Lepidurus Couesi*.

simple eye retained from the Nauplius stage. The number of body-segments varies greatly, and the body is usually protected by an ample shell consisting of two valves closed by an adductor muscle. In the group represented by Branchipus and the brine shrimp (Artemia) there is no shell. These crustaceans are very primitive, and apparently are the ancestral forms of the class Crustacea (q.v.), their limbs being much like the parapodia of annelid worms. A Cambrian form (Protocaris) is supposed to be allied to Apus. All the members of this order hatch in the Nauplius stage, and after a series of molts attain the adult form. The phyllopods live in pools liable to dry up in summer. Their eggs are of two kinds, summer and winter, the latter being protected by a dense shell, so that they can dry



PHYLLOPODA AND LARVÆ.

Adult of *Apus æqualis*, and (a) Larva of *Apus cancriformis*. (b) Nauplius of *Artemia salina*.

up and live for months or years, the young hatching when the eggs are moistened by the refilling of the pools or ditches. In some species the males have not yet been found. Consult Packard, *A Monograph of North American Phyllopod Crustacea* (Washington, 1883).

PHYL'LOTAXY (from Gk. *φύλλον, phyllon*, leaf + *τάξις, taxis*, arrangement). Leaf arrangement; that is, the methods in which leaves are disposed upon their axes. See LEAF.

PHYLLOXE'RA (Neo-Lat. nom. pl., from Gk. *φύλλον, phyllon*, leaf + *ξηρός, xēros*, dry). An insect of American origin (*Phylloxera vastatrix*), which belongs to the aphid family, and which, accidentally introduced into France about 1859 upon native American vines, spread through the principal vine districts of Southern Europe, causing enormous damage. It has further spread into Algeria and through Southern Russia into the adjoining countries of Asia. It has also been carried into New Zealand and South Africa, as well as portions of Australia. In the United States it was at first known only in the region of the Rocky Mountains, but was afterwards found in California, where it is confined to those vineyards in which the European vine is grown from its own roots.

The Phylloxera is indigenous to North America, where it has always existed on the wild vines. It occurs in four forms, the leaf-gall form (gallicola), the root form (radicicola), the winged or colonizing form, and the sexual form. The sexual insect lays the winter egg on the old wood. The young one hatching in the spring proceeds to a young leaf and locates itself upon the upper surfaces, gradually forming a gall about itself which projects from the lower side of the leaf. It reaches full growth in fifteen days, and fills its gall with small yellow eggs, from 500 to 600 in number. These eggs hatch in eight days, and the young migrate to all parts of the vine to form new galls. Six or seven generations of these wingless females follow one another through the summer, frequently covering the leaves with galls. At the approach of cold weather the young proceed to the roots, remaining dormant until spring. In the spring the root is attacked by a series of generations of wingless females which produce swellings upon the rootlets. During the late summer and fall some of the root lice give birth to winged females, which escape through the soil and fly to neighboring vines, laying their eggs on the bark. From these eggs the sexual generation issues, and the life cycle is begun again. The root form, however, may proceed in successive broods for a number of years, as is the case with the European vines on which the leaf form rarely occurs. The insect is spread by the flight of the winged females, by the migration of the root-lice through cracks in the soil, and by the carrying of the leaf-gall lice by winds, by birds, and by other insects, and further by the shipping of infested rooted plants or cuttings bearing the winter eggs. The leaf form is especially noticeable upon American vines, and is common upon the wild vines. The root form is rarely seen, but is the cause of the only severe injury to the plant. When occurring plentifully, the death of the vine in a few years is certain. The root lice first produce enlargements on the rootlets, extending their work to the larger roots. The leaves [illegible] and broken and finally die and rot. The vine stops growing, the leaves become sickly and yellowish, and since the Phylloxera disappears from the dead roots, the cause of the death of the plant is frequently obscure. The European vine (*Vitis vinifera*) is particularly subject to the attacks of the root form, while most American vines, although frequently carrying the leaf-galls, are more or less immune to root attacks.

The remedies used for this pest are the subterranean injection of bisulphide of carbon, and the submersion of the roots by inundating vineyards at certain seasons of the year by water. The standard preventive now employed all over the world is the use of American vines as stocks upon which to graft the susceptible European varieties. The immunity of the American vines seems to be due to the thicker bark covering of the roots, and to a greater natural vigor. The chief resistant varieties of American vines are the Æstivalis, the Riparia, and the Labrusca. Some American vines, however, as the Delaware, are almost as susceptible as the European vines. The varieties of the Æstivalis most used are the Herbemont and Cunningham; of the Riparia, the Clinton, Taylor, and Solonis. Consult Marlatt, *Principal Insect Enemies of the Grape* (Washington, 1898).

PHYLOG'ENY (from Gk. *φῦλον, phylon*, tribe + *-γένεια, -geneia*, production, from *γίγνεσθαι, gignesthai*, to become). While ontogeny (q.v.) is a term expressing the development (embryology) of the individual, phylogeny means the development or genetic history of the members of the group or class as a whole. The conception of such a process did not arise until a multitude of facts had been accumulated during the study of the embryology of different animal types, the results being further checked and complemented by the facts of paleontology. The doctrine or theory of phylogeny, then, rests (1) upon a series of life-histories of animals, including their embryonic and post-embryonic stages of development; (2) upon what we know of the geological succession of animal forms; and (3) upon the theory of descent. Phylogeny is the equivalent of genealogy, and involves the idea of blood-relationship. A genealogical tree of a single human family, when carried out through many generations, is almost indefinitely branched and subdivided, the members or descendants from the earliest human pair affording an instance of divergent evolution. The ancestral tree or pedigree of any class of animals is a matter of theory, but the facts of affinity and homology are so numerous and natural that the theory is fairly well grounded. The phylogeny of any group is an expression of one's view of classification, and since in respect to many groups there is a divergence of opinion as to the systematic position of this or that member, so the views as to the pedigree of certain classes or general groups differ with different systematists. The success of the endeavor to work out a phylogeny of any group depends very largely on knowledge of the earlier fossil forms; yet each attempt leads to the more careful study of this or that characteristic, to tracing its growth, development, and final disappearance, or replacement by a later acquired feature, while the mental discipline resulting tends to render the work of the systematist more philosophical. See PALEONTOLOGY; EVOLUTION.

PHY'LUM (Neo-Lat., from Gk. *φῦλον*, tribe). A term given by Haeckel to the primary divisions of the animal and vegetable kingdoms, which has now generally superseded the old terms 'sub-kingdom,' 'branch,' and 'type.' A phylum is a primary group either of animals or plants, all the members of which are supposed to be blood relations descended from one and the same stem, or ancestral, primitive form. The members inherit a mode of development, larval or nepionic stages of post-embryonic development, and adult structures which taken together make them to differ from those of other phyla. See CLASSIFICATION OF ANIMALS; PHYLOGENY.

PHY'SA (Neo-Lat., from Gk. *φύσα*, pair of bellows, breath, bubble). A small pond-snail abounding in quiet fresh waters throughout the warmer parts of the world. It is closely allied to the Limnæa, but the whorls of the amber-

PHYSA.

colored shell revolve from right to left, instead of from left to right as is the rule among spiral shells. A very wide-spread species in the United States is *Physa heterostropha*.

PHYSA'LIA. See PORTUGUESE MAN-OF-WAR.

PHYS'ALIS (Neo-Lat., from Gk. *φυσαλλίς*, *physallis*, plant with husks like bladders, bladder, from *φυσᾶν*, *physan*, to blow, from *φῦσα*, *physa*, bellows, breath, bubble). A genus of annual and perennial herbs and shrubs of the natural order Solanaceæ, remarkable for the calyx, which becomes large and inflated after flowering is over, and incloses the ripened berry. The species are natives of temperate and warm climates, and widely scattered over the world. The common winter cherry (*Physalis Alkekengi*) is a peren-

WINTER CHERRY (*Physalis Alkekengi*).

nial, native of Southern Europe and a great part of Asia, growing in vineyards and bushy places. The berries, which have a sweetish subacid taste, are often eaten. Among the American species, perhaps the following are best known: The downy winter or ground cherry or *Physalis pubescens*, *Physalis Peruviana*, *Physalis Philadelphica*, *Physalis angulata*. Some of these are cultivated in gardens to a small extent. Their fruits make good preserves.

PHYSICAL FORCE PARTY. In British politics, the term frequently applied to the party of Young Ireland which advocated physical force to procure the repeal of the union with Great Britain, after O'Connell in 1843 had countermanded the Clontarf meeting which had already been proclaimed by the military authorities, and on his arrest a week later had issued a manifesto advising the people not "to be tempted to break the peace, but to act peaceably, quietly, and legally."

PHYSICAL GEOGRAPHY. See GEOGRAPHY; PHYSIOGRAPHY.

PHYSICAL OPTICS. See LIGHT.

PHYSICAL SOCIETY, AMERICAN. A learned society organized for the advancement and diffusion of the knowledge of physics. It is one of the affiliated societies meeting with the American Association for the Advancement of Science. It also holds four meetings a year for the reading and discussion of papers upon the subject of physics.

PHYSICAL SOCIETY OF EDINBURGH, ROYAL. A learned organization of Scotland instituted in 1771 and incorporated by royal charter in 1788. Its object is the advancement of physical and natural science, including anthropology, paleontology, and meteorology. Discussions take place at monthly meetings held in the Philosophical Institution, Edinburgh, where the society possesses a large and valuable reference library. The membership is divided into three classes, ordinary fellows, corresponding fellows or non-resident members, and honorary fellows, the number of the last named being limited to fifteen. For over a century the society did not print its transactions, but now publishes an annual volume of *Proceedings*, 16 volumes being issued before 1903.

PHYSICAL SOCIETY OF LONDON, THE. A learned society founded in 1874, with its office and reference library in the Physical Laboratory of the South Kensington Museum, which has since transferred its official headquarters to Burlington House, London. Its object is to promote the advancement and diffusion of a knowledge of physics, and for that purpose to have papers read, new apparatus shown, and experiments tried at its meetings, which it holds fortnightly. The society publishes *Proceedings*, which are issued quarterly, and contain the more important papers read at the meetings, as well as the official records of the society.

PHYSICAL TRAINING (ML. *physicalis*, from Lat. *physicus*, from Gk. *φυσικός*, *physikos*, relating to nature, from *φύσις*, *physis*, nature, from *φύειν*, *phyein*, to produce; connected with Lat. *fio*, I was, Skt. *bhū*, to become, OHG., Ger. *bin*, AS. *bēo*, I am, Eng. *be*). A term in its largest sense including (1) the training of muscles of the body for the acquiring as well as the preservation of health; (2) the employment of the mind as a relaxation from work; (3) the physical exercise of the body as a whole as a means to health and happiness. This does not include training aimed at the enlargement of the muscles alone, which often results in ill health, since most great athletes use up their vitality early in life and die in middle age; nor does it include, except indirectly, the cultivation of certain inherited weak parts of the body, since here again

direct medical advice is the only safe plan to follow.

First of all, certain laws may be laid down. (1) The best exercise is always attained by playing a physical game, as contrasted with gymnasium apparatus, since the game not only stimulates all the functions of the body which otherwise are checked by the sedentary life of most human beings, but it also occupies the mind and thoughts, which, being thus turned away from the cares of life, are restored and refreshed. (2) Such games and exercise should be practiced in the open air, as contrasted with the same practiced within doors, since the air of outdoors is fresher, more stimulating, freer from dust and all substances which, taken into the lungs, do harm. (3) Such exercise should take place in the daytime, as contrasted with the night, since again sunlight has direct physical benefits that are lost when the sun has set. (4) Such exercise should be taken regularly at the same time every day, since a little regular work once a day is better than a large amount once a week, or irregularly.

A game played regularly out of doors in the daytime is therefore the ideal form of physical culture. Yet for a thousand reasons this best form may be impossible. Next best is a game outdoors at night, and after this a game indoors in the daytime. Again, if games are impossible, there are many forms of exercise which can be carried on in the daytime out of doors, and those should be chosen which require the greatest mental attention, in order to rest the mind as much as possible. Next in order would come physical exercise, exclusive of games indoors, and in the daytime, and finally, least important of all, but still infinitely better than nothing, certain physical exercises indoors during the night time. It is manifest at the start that the great body of humanity is confined to this last, but properly carried out it is itself sufficient to preserve health and often to bring back health to those who have lost it.

OUTDOOR EXERCISE.

GAMES. The best exercise in the world is unquestionably obtained in the game of polo. The entire body is at work all the time; every muscle, every nerve, is used constantly; no part of the body is neglected. In addition to this no man can play the game and keep his mind on business; for not only must all the brain he has be devoted constantly to the play, but he has under him another personality—the pony—which requires constant watching and direction. When the game is over the physical body is thoroughly exercised, the mind has been employed to its unbounded relief, and the whole man, physically tired, is renovated as nothing else can renovate him. Polo, however, is very expensive and therefore confined to the few. Next in order of importance would come the game of football, which covers all that has been said of polo, except that there is no other intelligence than that of the individual himself to guide. As in polo, football exercises all parts of the body, occupies the mind, with its absorbing interest in organization, combination—team play as it is called—and with the constant attention required to develop the best results for the individual himself. Again, this game is limited to young men, both because of the time required to practice, and because middle age too often makes the human machine incapable of enduring the physical strain.

Lacrosse comes next in importance. It has many of the good qualities of the two first-mentioned games, and it certainly occupies the mind. But a moment's reflection will show that in lacrosse the legs and leg muscles are developed at the expense of the chest, back, and some abdominal muscles. Lacrosse, however, is also confined to young men as a rule. Lawn tennis is more available for the average man; it has the advantage of being open to women and requires less training, less preparation, fewer players, and a shorter time each day. The expense is much less and its availability is therefore much greater. Again, however, one side of the body is exercised and therefore developed at the expense of the other, which is a serious objection, and also an element is wanting that plays an important part in the games already mentioned. In polo, football, lacrosse, and such games the element of personal contact is a most beneficial factor, even though it adds materially to the danger of the games. When injuries occur they are to be deplored, but they do not destroy the good there is in the games, and the moment the personal contact feature disappears, just so soon does the individual lose all the training in self-reliance, self-control, dignity, forbearance, and courage, which are as important in physical culture as are digestion, good circulation, and normal muscles. The loss of these in such games as lawn tennis is a serious drawback, and yet, following the principles already laid down, lawn tennis is infinitely better than nothing. The game can be played almost three-quarters of the year in the northern half of the United States and all the year round in the southern half. Baseball, considered from the point of view of physical culture, is not equal to any of the games already mentioned. It is first irregular in its muscular development; then, the very nature of the game requires sudden unnatural spurts of exercise with many periods of nerve-straining delays interspersed. Golf is now thoroughly established in this country, and becomes much more available as a means of physical training than any of the games so far mentioned because it is possible and feasible for many men and women. It has not the physical culture that other games have, because it involves no personal contact and because it is slight in its development of muscular tissue. And yet for the present purpose it is very valuable, since men and women of all ages from childhood to old age can play it, and it is available nearly the entire year over the whole of this country. Furthermore, if played regularly, it furnishes a training to the man who could not stand the more vigorous demands of other games.

Ice sports may be compared in merit with lacrosse. They offer the invaluable quality of being available at a time when most outdoor games are impossible on account of weather conditions, and as such they are the winter equivalent of other sports. The open air, the stimulant to circulation, the optimism engendered by the bracing qualities of the wintry out-of-doors are all valuable, but the limited time of their use confines them to the class of substitutes for other forms of physical culture.

In a general way, track sports and rowing cover the other forms of games for out-of-doors,

and both of these should come last in any physical culture category, since they have certain distinctly meretricious elements. Rowing in eight-oared shells, in four-oars, in pairs, in singles involves racing—competition—which, good in other sports, works for evil here. There can be no question that the strain of a boat race of any kind is injurious to the heart and the lungs. In contradistinction to other games, rowing is one continuous strain and effort from start to finish. There is no respite, no temporary delay where for an instant the organs of the body can snatch a little rest. And the same is in a measure true of running of all kinds, while the added disadvantages present in all track sports is manifest in the absence of any personal contact.

Walking, much abused as it is, will do much for health if properly conducted. But walking, as here considered, is different from the employment of 'shank's mare' to conduct a body from one point to another. In the first place, the walk should be taken at the same time each day. The individual should dress for it in light, loose clothing to give the freest possible play to all the muscles. The head should be held up, shoulders well back, chest thrust far forward, and the arms bent a little, while the hands grasp two banana-shaped pieces of cork like the handles of a bicycle. The stride must be long and swinging, starting from the shoulders and including the hips, so that the whole body swings forward on one side and then on the other as each step is taken, and the side and abdominal muscles are kept constantly at work. The pace should be fast and there should always be a definite point to be reached at a definite time. One would say that any human being, no matter how busy he might be, could find time for a half hour's walk during the day or night, and if he would prepare for it in suitable clothing and follow it out as an exercise, and not as a dilatory way of getting an opportunity to think over some problem of business, he would receive material benefit thereby. Its great disadvantage, however, is that even carrying out the stride, the position of the body and the regularity of the exercise, he still secures no rest for his mind, since the mere physical act of walking does not necessarily require constant mental attention. It only requires a problem of life that is sufficiently absorbing to divert the thoughts from surrounding objects or from attention to the operation of walking to the problem itself. In fact, walking often helps the mind to work. Riding has this advantage over walking, that it does give the mind relaxation, since the management of the horse requires a certain amount of attention. But, again, riding has not the amount of physical exercise in it that walking has when the latter is properly carried out, and riding is not as easily undertaken in view of the expense of keeping a horse. In the order of importance as regular outdoor forms of special development exercise come swimming, bicycling, running, shot-putting, hammer-throwing, and so on. They are all good—that is, better than nothing, better than the same things indoors—when properly and regularly carried out; but they all have distinct disadvantages. For example, bicycling develops the legs without doing much for arms or shoulders, and the bicyclist too often leans heavily upon the handle-bars, bending far forward, compressing his lungs, training his shoulders to become 'round,' and forgetting entirely the abdominal muscles that need the regular gentle development of constant movement. Swimming, which is very general in its all-round use of the body, has its distinct advantages. But it can only be undertaken at limited times in the year, and then only by him who lives near the sea or some large body of water. It is questionable for the individual, since there are many people whose circulation is far from being benefited by bathing in the constant manner which is necessary if any physical good is to come of swimming as a regular exercise.

INDOOR EXERCISE.

Sparring is perhaps the best of indoor games. It is a most admirable exercise. It uses all the muscles of all parts of the body. The swaying of the trunk, the quick movements required in all the leg muscles, the extraordinary variety of movements about the arms, neck, back, and head, all keep the muscles in good condition and stimulate circulation, respiration, and good digestion. But in addition to this it can be seen that no one who is boxing can give much thought or attention to his business, or to anything but the game in hand. It needs only a straight blow on the nose to wake up the delinquent and make him give his undivided attention to the matter in hand. Here is a game that in many ways surpasses bicycling as a means to physical culture, while bicycling, on the other hand, has the one advantage of taking the individual out of doors. Wrestling has many of the good points of sparring and as such is a good form of physical culture. Yet here the teacher is more necessary than in most games. The danger of straining muscles and weakening tendons is very great, since a contest is of course necessary, and the desire for victory prevents one or the other of the combatants from giving up when a strain becomes the penalty for not doing so. Yet both these games develop all parts of the body equally and thoroughly.

Rackets, court tennis, and handball are all capital indoor games. They employ the mind and can be undertaken for half an hour a day regularly at a certain time. The disadvantage in them over such exercises as sparring is that they develop one side of the body to the detriment of the other. A right-handed player, for example, is constantly using his right arm with the racquet, and thus develops his whole right side without bringing the left side into play to any great extent. Naturally the circulation, the respiration, and the general relaxation of both mind and body go on, but the muscular development needs some specific exercise for the left side after the game is over, if the normal of physical culture is to be attained.

Fencing also has the same one-sided development, yet it adds the ease and grace of movement which make it one of the most valuable means of physical culture for women that can be used under cover of a roof. Like single stick and the many forms of offense and defense with a weapon, it really has qualities that few games can boast. The agility, quickness, grace, and *finesse* that are required have to do with physical culture in its highest sense.

SPECIAL DEVELOPMENT EXERCISES.

To go thoroughly into this large branch of physical culture would be impossible here. It is possible, however, to suggest lines of work. The pulley-weights and dumb-bells are so monoto-

nous that they do not occupy the mind, and they therefore lose a part of their force as means toward physical culture. The punching bag, on the other hand, is really a game which is played with an inanimate but very vigorous adversary. Again, however, it is necessary to add, in order to preserve a proper sense of proportion, that this is not equal to a game out of doors in the daytime and never will be; but then, on the other hand, it is so much better than nothing that it often means in so many words the difference between health and sickness. In like manner might be catalogued the apparatus of the gymnasium in the order of their desirability, such as rowing machines, parallel bars, pulley-weights, and so on. They all have their uses; they can all be set up in any private house, and they are all of service in maintaining health when nothing better can be had. Their use is precisely and only this: Exercise must be taken regularly every day in some form to stimulate circulation and respiration; exercise must be given the mind along other lines than those followed in daily life. Either the home or the club gymnasium will be better than nothing, as a little regular exercise day by day of whatever kind is better than none at all. One other method offers itself for general consideration and that, too, is better than nothing. Yet it requires what is found only here and there in mankind—the capacity for absolute regularity day by day, every day of every year. There seems to be something in the human make-up that militates against regularity, and in the least beneficial and yet easiest of forms of physical culture regularity is the whole story. Forms of exercise without the use of apparatus are best suggested by the United States Army *setting-up exercises*. They include the *Swedish system*, the *Delsarte system*, and all the other innumerable forms of setting-up exercises which have been invented. In considering these, two very different points of view must be considered. (1) If a portion of the body is weaker than all other portions—for example, if a broken leg, now healed, needs special attention to bring the long unused muscles up to standard—these forms of exercise ought to be taken under the advice of a physical culture instructor, since a thorough knowledge of anatomy is needed to point out just what exercises are most efficacious. (2) If the maintenance of general health is desired, then no teacher or instructor is at all necessary. It only needs to consider the muscles of the body. For example, before bathing, lie on the floor on your back and (1) rise to a sitting position twenty times; (2) raise the legs to a perpendicular position twenty times; (3) turn over, and, touching only the toes and hands to the floor, thrust the body upward by straightening the arms twenty times; (4) stand up, and, keeping the legs straight, bend forward and touch the finger tips to the floor twenty times; (5) rise on the toes twenty times; (6) keeping the body straight and upright, bend the knees and sink down toward the floor twenty times, rising again by straightening the legs; (7) take hold with one hand of the end of a door and grasp with the other the door frame when the door itself has been opened about one-quarter of a quadrant; standing thus, allow the body to fall forward so that the chest passes through the opening and the shoulders are thrust far back until the shoulder-blades touch; do this twenty times; (8) place the hands on the hips, stand straight, and then bend forward as far as possible twenty times, backward twenty times, to the right side twenty times, to the left twenty times; (9) standing straight, go through—twenty times each—the motions of raising the arms at full length above the head, backward, forward, and down. When a child or youth or a young girl is in question the advice of an expert is, of course, almost necessary.

GENERAL CONSIDERATIONS.

In conclusion it is necessary to suggest a few general rules which apply to all forms of exercise for physical training. Food is the principal question. Eat three times a day and always at the same hours. Eat simple meats and vegetables, a light breakfast, a moderately light lunch or midday meal, and a moderately heavy evening meal. Never eat at any other time. By simple foods is meant meat and vegetables cooked simply without sauces and extra substances which only confuse the digestive organs when they begin their wonderful work of turning food into blood and tissue. Drink plenty of water between meals, but little or none at meals. Drink alcoholic drinks or not as you like, or as your belief dictates; but remember that temperance is neither too much nor too little, and the actual amount per day which is really temperate must in each case be decided by the individual. There have been men who drank temperately all their lives and lived to be ninety and the quantity per day which they consumed would have killed another man in a year. Temperance is the only rule, and as what is temperate for one is intemperate for another, each must decide for himself. Clothing has much to do with physical culture. In parts of the United States the climatic changes are great, but it should be remembered that our houses are of about the same temperature all the year round. Therefore the underclothing should be of the same thickness all the year round and the outer clothing should fit the outer climate of the day. But more important perhaps than this is the rule that underclothes should be changed once every day. After the regular occupation of the day, just before dinner or supper, say at six or seven o'clock, every man and woman should put on a clean set of underclothing. The physical benefit is immense, but it does not compare with the mental rest and recreation that will result from this simple aid of physical culture. Bathing is another necessity. Each man and woman immediately after rising and taking fifteen minutes of exercise, should take a shower bath of first warm and then cold water, or if a shower is impossible, an ordinary bath in a tub. Never neglect the final cold water. It closes the pores of the skin and avoids the danger of taking cold. The feet are perhaps as important as anything. Napoleon said that an army with good shoes could do anything he asked of it. So might a man say that his body will do anything he asks of it if his feet are well cared for. Buy good shoes, and take care that they are not too large, and are well made. Keep them carefully and change them at least once a day in the early evening. Have several pairs so that the shoes can have a rest every other day. Finally *regularity* in sleeping, eating, dressing, and exercising is the important detail. Such are the extraordinary powers of the human body that it responds to regularity, to habit, as to nothing else. It be-

comes accustomed to certain things at certain times and it will serve you better than you serve it, if you will but treat it temperately, regularly, and generously. If you sleep regularly, eat regularly, dress regularly, exercise regularly, you can put your physical and mental body to such strain in the way of work as would kill the irregular man in a few months—and that is after all the substance of all physical culture.

PHYSICIAN (OF. *physicien, fisicien*, from Lat. *physicus*, from Gk. *φυσικός, physikos*, natural philosopher, physician, from *φύσις, physis*, nature, from *φύειν, phyein*, to produce). In law, one who has complied with all State regulations in regard to the study of medicine, and who may lawfully practice medicine. Most States require a medical student to pass a State examination satisfactorily, and thereupon grant a license to practice to successful candidates. Such provisions are constitutional. A person who holds himself out as a physician is considered to represent that he has the ordinary skill of one of his profession. Lack of skill or negligence on the part of a physician, resulting in injury to a patient, is called malpractice (q.v.). It is generally held to be optional with a physician as to whether or not he will attend a person calling him.

The relation of a physician and patient is a confidential one, and the former is bound not to divulge any of the secrets confided to him by the patient, even on the witness stand. The statutes of each State in regard to the practice of medicine should be consulted. See MALPRACTICE; EVIDENCE.

PHYSICK, fiz'ik, PHILIP SYNG (1768-1837). An American physician, born in Philadelphia, educated at the Friends' Academy. In 1788 he went to Europe, studied with John Hunter, and was admitted to Saint George's Hospital in 1790. In the same year he received a diploma from the Royal College of Surgeons, and assisted Dr. Hunter for one year. Returning to Philadelphia in 1793, he was appointed physician to the yellow-fever hospital at Bush Hill; in 1794 surgeon to the Pennsylvania Hospital; and the following year, on the recurrence of the yellow-fever epidemic, he was placed once more in charge of the Bush Hill Hospital. In 1801-16 he was surgeon to the Philadelphia Almshouse Infirmary; in 1805 professor of surgery in the University of Pennsylvania; in 1819 called to the chair of anatomy, which he filled until 1831; in 1821 consulting surgeon to the institution for the blind; in 1824 president of the Philadelphia Medical Society. In 1825 he became a member of the Royal Academy of Medicine in France, and in 1836 honorary fellow of the Royal Medical and Chirurgical Society of London. He was the author of *Deapoplexia* (1792).

PHYSIC-NUT (*Jatropha*). A genus of about 70 species of tropical shrubs and trees of the natural order Euphorbiaceæ, characterized by alternate, stalked, angled, or lobed leaves, corymbs of flowers on long stalks, and the acrid oil of their seeds. The common physic-nut (*Jatropha Curcas*) of the East Indies, introduced into the West Indies, southern Florida, and other warm parts of the world, is a small, much branched, rapidly growing tree or bush with a milky juice. It is used for fences in many tropical countries. The expressed oil, commonly called jatropha oil, is used for illuminating purposes, and has been used in medicine. The French or Spanish physic-nut (*Jatropha multifida*), an American shrub with many-lobed leaves, yields an acrid oil, called oil of pinhoen. To this

PHYSIC-NUT.

genus belongs the pinoncillo (*Jatropha lobata*) of Peru, the roasted seed of which is an agreeably flavored food. Incisions in the stem of this tree allow the escape of a clear bright powerfully caustic liquid which after some time becomes black and horny, but retains this property for years. Physic-nettle (*Jatropha urens*), a native of the Southern United States, has similar qualities.

PHYSICS (from Gk. *φυσικά, physika*, nom. pl. neu. of *φυσικός, physikos*, relating to nature). Physics is one of the successors of the study formerly called natural philosophy, or the science of the phenomena of nature as revealed to us by our senses and as interpreted and systematized

by our intellects. The name itself is the plural of the word 'physic,' which was used as early as the fourteenth century to mean natural philosophy, but which afterwards became restricted to mean the science of medicine, and finally to mean a medicine or drug itself. While physics in its modern sense comes closely in contact with chemistry, astronomy, and many other sciences, it is impossible to state in words its exact scope. It may be said, however, in general that the study of physics includes the phenomena of acoustics, of heat, of light, of electricity and magnetism, and of mechanics to a certain extent. Within recent years many subdivisions have been made both in physics as a general study and also in its various parts. The subjects pertaining to the nature of solutions are now included in physical chemistry; the spectroscopic examination of the sun, stars, etc., together with the related theories, forms the science of astrophysics; the observations and theories of earthquakes, heat conduction on a large scale, volcanoes, etc., are now studied under the name of geological physics. Practical applications have been made of many observations in physics, and there are schools of engineering devoted to the study of these matters. Among the branches of engineering are mechanical, hydraulic, steam, and electrical.

The fundamental idea of physics is that we learn by means of our senses certain facts in regard to natural phenomena, which are independent of time and space. These last two concepts, namely those of time and space, are considered as intuitive. The name matter is given provisionally to whatever is the cause of our sensations; but it is *defined*, naturally, in terms of its properties. There is not necessarily involved any assumption as to the reality of matter; rather, there are found certain mathematical expressions, certain differential equations, which express our knowledge of nature, but which we interpret in such language and with such ideas as correspond to our mental pictures. Associated with this idea there are two great divisions of physical methods; one may be called the laboratory method, the other the method of mathematical physics. (See LABORATORY.) The laboratory method consists, first, in making a series of observations and amassing information in regard to phenomena, but further in seeking to obtain a generalization with which the observed phenomena may be in accord. The object and scope of mathematical physics is well expressed by Professor Poincaré in his introduction to the *Reports of the International Congress of Physics* (Paris, 1900). The fundamental method is to devise certain postulates and to state such axioms as will lead by rigid mathematical processes to formulæ which may be compared with observed phenomena. Thus by means of the methods of logic conclusions may be drawn connecting many phenomena which on their face are unrelated.

HISTORY OF PHYSICS. It is remarkable to note how few facts other than obvious ones were known to the ancients in regard to nature, and also to find how few instruments were available for what may be called scientific observation. Beyond a doubt simple forms of instruments were known for the measurement of time, such as water-clocks, sun-dials, etc., and the Chinese at least had a knowledge of some of the simple properties of a magnet. The law of the reflection of light was generally known and lenses were in use for various purposes. The law of the lever was known to Archimedes, as were also certain of the laws of hydrostatics. There was a knowledge of harmony in music more or less incomplete. A few observations are also noted in regard to electric attraction and the facts of meteorology.

Up to the Middle Ages there are few if any facts to be recorded in regard to the growth of natural philosophy, because the Romans were content with the knowledge left them by the Greeks, and the intellectual activity of the Arabs seemed to be concentrated, as far as physics is concerned, in the person of Al-Hazen, who was interested largely in optics. There was a revival of interest in nature during the thirteenth century, as shown by the work of Roger Bacon and Peregrinus. In the sixteenth century Copernicus lived, and he was followed by Galileo, Kepler, Stevin, Gilbert, and others.

The effect of the life and work of Galileo in Italy and of Gilbert in England cannot be overestimated. There was a universal revival of intellectual activity and a universal interest in the study of natural phenomena. Each of these two men emphasized the need of experimental study and the futility of logic apart from observation. Galileo's greatest contribution to physics was the statement of the principles of mechanics. He was succeeded by pupils whose interest and influence was so great that they led to the establishment of academies and learned societies throughout Europe. With the appearance, however, of Huygens's *Horologium Oscillatorium* (1673) and Newton's *Principia* (1687) physics came to the front as the most important of the sciences. The methods used by these two men, both in their observations and in their statement of laws of nature, have served as the models for succeeding generations. They were followed by two schools, one interested in the mathematical development of mechanics, the other interested in the purely experimental side of the subject, whose legitimate predecessors were Torricelli, Pascal, Boyle, and Guericke.

MODERN TIMES. The development of our present knowledge of physics is more fully described under the separate headings of its various subjects; namely, acoustics, heat, light, electricity, and magnetism. It should be sufficient in this place to refer to a few names in connection with each of the subjects. Our accepted ideas in regard to the nature of heat and heat effects are due to the researches and theories of Black, Rumford, Davy, Carnot, Clausius, and Joule. In light we owe most to Young, Fresnel, Fraunhofer, Kirchhoff, and Stokes. In the subjects of electricity and magnetism a long list of names should be mentioned, but among these those of Volta, Cavendish, Ampère, Oersted, Faraday, Henry, Gauss, Weber, Maxwell, and Hertz are easily the most notable. To Helmholtz alone, it is only fair to say, all of our accepted ideas of the theory of sound are due. The names of no living men have been included in the above summary, but any such list would be incomplete without the addition of the names of Kelvin, Rayleigh, Lorenz, J. J. Thomson, and Röntgen, who have contributed so much to the most recent ideas in regard to the fundamental concepts of nature.

Previous to the nineteenth century there were

three great principles of physics which were firmly established and which deserve to be called laws of nature. These were the law of gravitation, the principle of the conservation of matter, and that of the conservation of momentum. Some doubts have recently arisen as to whether the weight of a definite quantity of matter remains unchanged as its state is altered, but there seems to be no reason for doubting the principle of the conservation of matter itself. The most notable fact in the history of physics during the nineteenth century was the development of the principle of the conservation of energy and its application to all fields of science. This great development was due largely to the efforts of J. R. Mayer, Helmholtz, and Joule. Other great principles, such as the second law of thermodynamics, were expressed in words, and will be found discussed in other places. The kinetic theory of matter was also elaborated and established on a firm basis.

Beginning with the discovery of the X rays by Röntgen in 1895 and of the radiation from uranium by H. Becquerel in 1896, there has been a progress in physics and in our knowledge of the properties of matter which has been one of the most striking facts in the whole history of science. The point of departure in our new knowledge comes from the epoch-making discovery by J. J. Thomson that in their passage through air both the X rays and those from uranium make the air a conductor for electric currents. This discovery led at once to investigations by observers the world over in regard to the nature of the ionization of air and of the radiations which produce it. It was soon found that many substances other than uranium had this same power of emitting radiations which would ionize a gas; such were thorium, and the newly discovered elements, radium and polonium. These substances are said to be 'radioactive;' and it was observed that nearly every body in nature was 'active' to a greater or less degree. The properties of the radiations themselves were carefully studied and analyzed, and their properties other than that of ionization were investigated. There are always present in the radiations from such bodies both positively and negatively charged particles of matter whose velocities vary within wide limits. When the velocities of the negatively charged particles as produced in various ways were studied, a most remarkable fact was observed. Attention had been called many years ago by J. J. Thomson to the fact that if a charged sphere were moving rapidly it would have an effective inertia greater than that which would be observed in case it were uncharged. In other words, an electrical charge in motion has an apparent mass quite apart from that of the matter carrying it; and formulas have been deduced by Thomson, Heaviside, and Abraham connecting this mass of the charge with the quantity of charge, its velocity, and its acceleration. It was observed in the case of the negatively charged radiations above referred to that their apparent mass was exactly that which would be calculated from the formulæ on the assumption that the mass was due entirely to the moving charge. This discovery renewed at once the theories of matter which had been advanced before, in accordance with which the inertia of matter is a property due to the motion of an electric charge. The name 'electron' has been given these charges when considered apart from matter, and a most interesting discussion of their properties and of the theories of matter based upon these is given in a series of papers by Sir Oliver Lodge in the *Electrician* (London) during the winter of 1902-03.

One of the great contributions of the nineteenth century to physics was the development of the idea of the luminiferous ether. The necessity of a medium for the transmission of the waves which produce the sensation of light had been recognized for many years and was clearly stated by Fresnel and others. Faraday had also come to the conclusion that a medium was necessary for the transmission, or rather existence, of electric and magnetic forces, and had suggested that possibly this medium might be identical with the one that carried 'light waves.' Maxwell showed by theoretical considerations that the velocity with which an electromagnetic disturbance would be propagated in the medium referred to by Faraday must be numerically equal to the so-called 'ratio of the electrical units,' and further showed from experimental evidence that this was equal to the number expressing the velocity of light. He also proved by a mathematical investigation that the electromagnetic waves were identical in all respects with those with which we are familiar in the phenomena of light, and thus established the fact that only one medium is necessary for the explanation of the phenomena of light, electricity, and magnetism. The connection between this ether and ordinary matter has been investigated by many observers, as described in the article on ETHER. The accepted theory at the present time is that the ether does not move as material bodies are carried through it; and this, in connection with the ideas of electrons, has been elaborated by Lorentz into a theory which is able to explain in the most satisfactory manner the phenomena of dispersion, metallic reflection, and stellar aberration. There are many difficulties, however, which still remain to be investigated in regard to the properties of the ether, in spite of the great progress marking the beginning of the twentieth century. If the inertia of matter is to be regarded as capable of explanation, as indicated above, from the standpoint of electricity, there still remain two great problems for solution. What is the nature of an electric charge? and what is the cause of gravitation? The development of physics at the present time is tending toward investigations of these two questions.

PHYSIOCRATS (from Gk. *φύσις, physis*, nature + *κρατεῖν, kratein*, to rule). A French school of political and economic philosophers, known to their own generation as *Les Economistes*, who wrote against the antiquated methods of the State in encouraging industry (see COLBERT), and in favor of agriculture, industrial freedom and natural liberty. The school flourished from 1756 to 1776. The founder and leader of the school was François Quesnay (q.v.), a noted surgeon, metaphysician, and, after 1749, physician to Madame de Pompadour. With Quesnay is often associated in the founding of the sect the name of Jacques Claude Marie Vincent de Gournay (q.v.), who did not, however, indorse the extreme views of the school respecting the paramount economic importance of agriculture. The most earnest disciples and indefatigable propagators of the Physiocratic doctrine were the elder Mirabeau, Mercier de la Rivière (1720-94), and Dupont de Nemours (q.v.), editor of the works of Quesnay and Turgot and of the Physiocratic journals. Among the statesmen, rulers, and princes of the time who accepted the main doctrines of the Physiocrats were first and most important, Turgot (q.v.), Minister of Finance under Louis XVI.; Charles Frederick, Margrave of Baden; Gustavus III. of Sweden; Leopold II., Grand Duke of Tuscany, and afterwards German Emperor; Stanislas of Poland; the Emperor Joseph II.; and Charles III. of Spain. With some of them the acceptance was little more than half-hearted, and the only monarch who made an earnest attempt to carry out their programme of reform was Charles Frederick of Baden. He tried to apply their principles in three villages, but finally abandoned the attempt.

The general doctrine of the Physiocrats was an extension to the economic sphere of the theory of natural liberty which Locke, Hutcheson, Shaftesbury, and others had applied to the sphere of politics and religion; but, unlike the British philosophers, the Physiocrats denied that the natural rights of the individual could be abridged by any social contract. Every man, they held, has a right to the free exercise of his faculties, so long as he does not infringe the like liberty of others, and this involves the further right to the undisturbed enjoyment of the property which results from the exercise of his faculties in productive labor. It follows from these rights that the sole function of government is to protect life and property and to administer justice, and no interference by the government with commerce and industry is permissible—in the classic phrase of the school, *laissez faire, laissez passer* (q.v.)—but within the restricted sphere noted above the Physiocrats advocated a strong monarchical government, a "legal despotism, tempered only by an enlightened public opinion."

The peculiar economic views of the Physiocrats seem to rest upon a confusion of wealth with material objects, leading to the conclusions that agriculture alone yields a surplus product—*produit net*—above the expenses of production; while manufactures and commerce, which merely change the form or position of raw materials, are barren. As agriculture is the only form of production yielding a value in excess of the cost of production, they advocated that taxes should be levied upon rent—which expresses or measures the 'net product'—so as to avoid the expense and friction attendant upon the shifting of the tax to this source when placed originally upon other objects. They thus gave to political economy the fruitful theories of surplus value and the single tax—*impôt unique*. (See POLITICAL ECONOMY.) The scientific virtues and defects of the Physiocrats may be traced to one and the same cause, the belief in a beneficent and absolute natural law governing the moral and social universe with the same rigidity and precision as the material universe is governed by physical law. This belief made them at once narrow but precise, systematic but unmindful of the difference between physical and psychical phenomena, careful in definition, distinction, and classification, but careless of the effects of customs, law, and the diversity of human motives. They have exercised a deep and lasting influence upon political economy, and it is now usually admitted that Quesnay, rather than Adam Smith, is to be regarded as the 'father of political economy.' Opinions differ regarding their influence upon the practical affairs of the day. They undoubtedly stimulated the study of agriculture, suggested several important agricultural improvements, called attention to the oppression of the peasantry and elevated their importance in the eyes of the nation, and secured a freer intercourse of trade—particularly in breadstuffs—within the French kingdom. In the early years of the French Revolution their doctrines exercised an appreciable effect upon the Constituent Assembly, but their most striking practical influence was exercised through Turgot (q.v.), who, while not a professed Physiocrat, made many earnest attempts, both as intendant of Limoges (1761-74) and as Comptroller-General of Finance (1774-76), to abolish the corvées and the guilds, to introduce free trade in corn, to reduce taxation, and to accomplish the general reforms which the Physiocrats demanded.

Among the most important publications of the Physiocrats are Quesnay's articles on *Fermiers* and *Grains*, published in the *Encyclopédie* of Diderot and D'Alembert; *Le droit naturel*, published with other of his writings in the *Physiocratie* (which gave the school its name), edited by Dupont de Nemours, and his *Tableau économique*, 1758, "the Bible of the Physiocrats," reprinted for the British Economic Association, London, 1894; Mirabeau's *Théorie de l'impôt*, 1760, and *Philosophie rurale*, 1763; Dupont de Nemours's *De l'origine et de progrès d'une science nouvelle*, 1767, published in his *Physiocratie;* Mercier de la Rivière's *L'Ordre naturel et essentiel des sociétés politiques*, 1767; and Turgot's *Réflexions sur la formation et la distribution des richesses*, 1770.

PHYSIOGNOMY (OF. *physiognomie, phisenomie*, Fr. *physionomie*, from Gk. *φυσιογνωμία,*

physiognōmia, *φυσιογνωμονια*, *physiognōmonia*, art of judging by the features, from *φυσιογνώμων*, *physiognōmōn*, one who judges by the features, from *φύσις*, *physis*, nature + *γνώμων*, *gnōmōn*, judge, from *γιγνώσκειν*, *gignōskein*, to know; ultimately connected with Eng. *know*). In general, the form and expression of the visage or face, especially when regarded as indicative of character; specifically, an art or system of reading character from the face. This system was framed by Lavater, and is related to that of phrenology as formulated by Gall and Spurzheim; it was extended and expanded in America chiefly by S. R. Wells in connection with O. S. Fowler, L. N. Fowler, and others. In its application the system involved temperament as determined from complexion, etc.; the general aspect of head and face, sometimes in comparison with those of animals whose traits the individuals were considered to imitate; the form, size, and prominence of particular features, etc. The chief bases of the system were assumed (1) localizations of functions in the brain, and (2) corresponding localizations in the external features. Later researches in cerebral and general anatomy and physiology have failed to establish most of the assumed localizations and correspondences, while modern students commonly regard facial forms and features rather as hereditary ethnic characters than indices of individual disposition; so that the current art may be defined as character-reading from facial expression. A good many modern students, among whom Cesare Lombroso may be regarded as the leader, distinguish between normal and abnormal types of physiognomy, and view the latter as indices of either degeneracy or reversion to lower ancestral types; and some writers have sought to combine certain classes of abnormalities in a 'criminal type' for the guidance of students, jurists, and statesmen. The recognized abnormalities include certain malformations of face and head, asymmetry of features sometimes analogous to that accompanying epilepsy or paralysis, excess or deficiency of hair and beard, unusual pigmentation, and various stigmata, either congenital or of later development. The coördination of these abnormalities with conduct forms a considerable part of the foundation for criminology (q.v.) as defined by Lombroso. The general form and expression of the visage are among the ethnic traits recognized in defining races and peoples. The facial angle, i.e. the degree of prognathism, is among the most useful measures both in comparative anatomy and in ethnology; the shape of the jaw, the conformation of the cheek-bones, the position of the ocular orbits, the number and character of the teeth, and the nature of the dermal appendages (hair, beard, brows, etc.) are also of primary importance as ethnic characters; while the superior expressiveness of the features of more advanced peoples is among the characteristics noted by the ethnologist.

PHYSIOG'RAPHY (from Gk. *φύσις*, *physis*, nature + *-γραφία*, *-graphia*, description, from *γράφειν*, *graphein*, to write). There is much difference in the usage of the term physiography. It is employed as a synonym for the older term physical geography; as a term to include a general introduction to science; for the study of the physical environment of life; and for the study of land forms alone, that is as a synonym for the recently proposed name geomorphology. In the United States the term physiography is rapidly coming to replace the older term physical geography, at the same time that a more scientific basis is being introduced into physical geography. In this sense, physiography is concerned with the study of air, ocean, and land, with the object of understanding their present condition and influence on life. To understand present conditions leads back into meteorology, oceanography, and geology; to appreciate their influence on life presupposes knowledge of history and biology at least. It is no uncommon belief that physiography is too complex, and drawing upon too many other subjects to have distinct boundaries, and hence to deserve the name science. It is true that there is no general agreement as to the exact boundaries; but this is by no means proof that physiography can have no boundary. Some one has said that geology is a study of the past. That is to say, a geologist, to appreciate his subject fully, must have knowledge as a physiographer; and a physiographer must know the past that he may use geology as a tool in his attempt to understand the present.

Astronomical Aspects. The study of physiography deals essentially with the earth—its spherical form, its envelopes of air and water, its cold crust and heated interior, and their influence on life. Yet no thorough appreciation of these conditons and influences is possible without a general knowledge of the astronomical relations of the earth. The earth as a sphere, and as a member of the solar system in which it so moves as to give day and night and the seasons, are facts of fundamental importance to an understanding of changes in the earth; and the spherical form of the earth, and the presence of heat among the members of the solar system, furnish adequate reason for a consideration of the hypotheses for the origin of the earth. This does not mean that the subject encroaches on astronomy; it is dealing with the earth, but it inquires of astronomy the reasons for terrestrial phenomena of vital importance, and applies these to an interpretation of the phenomena in their relation to life.

The Air. The influence of the air on life is universal. Its oxygen and carbon dioxide; the influence of its pressure; the effects of its density, for example, on the flight of birds; its water vapor; its winds and their effects—these are among the many reasons why a study of the air properly forms a part of physiography. The science of meteorology furnishes the explanations, and with these the physiographer needs to be familiar. In order that he may understand the distribution of life he should know why there is vapor, why winds blow as they do, why there are rainy and desert regions, and why there are storms. The branch of physiography that deals especially with this phase of the subject is climatology. If the climatologist studies only the causes of climate he becomes a meteorologist; but if his especial concern is the understanding of the laws of climate with reference to their influence on life, he is a physiographer. The study of the air has a bearing on other phases of physiography. Waves and ocean currents depend on air conditions, and to understand them calls for a knowledge of air movements. Rain, river floods, the difference between the topography of arid and moist lands, and the existence of glaciers, are among the fea-

tures of the land that depend upon a knowledge of the air for their proper appreciation. Each of these reacts on life. Thus, along several lines, it is evident that there is a phase of air study, calling for an appreciation of the science of meteorology, it is true, but with its main object the investigation of the influence of the air on the environment of plant, animal, and human life.

THE OCEAN. The temperature and movements of the ocean, dependent upon sun's heat and air movements; the tides, dependent on the attraction of the sun and moon; the composition of the ocean water, its depth, and the characteristics of the ocean bottom are among the important physiographic features of the ocean. Each of these has an influence on life. The ocean supplies vapor to the air; its vast expanse and its currents influence the temperature of the air and aid in those movements of the air by which the temperature and rainfall of the lands are profoundly affected. Life in the ocean as influenced by its environment; the effect of ocean influence on the life of the lands; the ocean as a barrier to the spread of life; and its importance to man in commerce and many other ways are among the subjects with which a physiographic study of the ocean is concerned. The oceans and the lands are profoundly interrelated. The waste of the land is carried to the sea by rain and rivers; and the oceanic agents are attacking the land along its border, forming many varied coast features. Changes in level of the crust lower parts of the land beneath the sea, and raise sea bottoms to form dry land. No study of the lands can promise the best results without a knowledge and appreciation of the conditions of the coast line and sea bottom. From this it is evident that the physiographic study of the ocean is broadly interrelated with the study of the land and air. The science of the study of the ocean is called oceanography; and, as in the case of meteorology, while the physiographer must understand the principles, his concern is far less with the science of oceanography than with the application of its principles to an understanding of their influence on life.

THE LANDS. There is a conflict of forces at the present time operating to modify the forms of the lands which themselves so greatly influence life. On the one hand contraction of the interior of the earth is causing changes in the level of the crust as a result of which continents are raised and ocean bottoms depressed, while mountain chains, volcanoes, plateaus, and plains are being made. On the other hand opposing forces are at work on the land removing the rocks that lie above the sea level and dragging the fragments into the sea. The weather disintegrates the rocks, the rains, rivers, and winds remove the fragments. Glaciers occasionally aid in this erosion, and the seacoast is the seat of further important work of this kind. The result of the opposing forces of elevation and destruction has been to produce a very complex land surface, and it is one of the most important provinces of physiography to understand this land surface and to point out its effect on life. For this phase of physiography the name geomorphology has been proposed. It is intimately related to geology and makes use of geological principles. It is by some considered as a branch of geology; that is, the geology of the present.

Many of the principles relating to the physiography of the lands are stated under other topics. (See RIVER; LAKE; MOUNTAIN, etc.) In this place only the scope of the subject will be indicated. The simplest land form is the plain (q.v.), the most extensive and perfect plains being on the sea bottom. They may be classified as constructional and destructional, the former being represented by elevated sea-bottom plains, lake-bottom plains, delta plains, flood-plains, etc.; the latter by plains of marine denudation, plains caused by lateral erosion of rivers, etc. In the beginning their surfaces are level, they permit the ready spread of animals and plants, and, if the climate favors, they are usually well suited to occupation by man. If newly formed, or young, the surface may be so level that water stands on it as lakes or swamps; but with increasing age the surface is drained, streams cut valleys, the flat-topped divides are narrowed, and the lakes and swamps are destroyed. In the development of these stream valleys, if the plain stands high enough above sea level, or base level, the rapid cutting along the channels permits the development of deep, steep-sided valleys. In these young valleys the vigorously working streams flow with rapid slope, and with occasional falls where hard layers are encountered. If the land is high above base level, that is, if it is a plateau, the young streams may so trench the land that travel across country is prohibited by the deep cañons. In such cases the interstream areas only are habitable and are chosen for roads and railways. With time the valleys broaden, the slopes become more gentle, and both the valley bottoms and sides invite settlement. Such a land surface is mature, and is well illustrated by the Mississippi Valley. There are few if any falls, the rivers are navigable, and they are bordered by flood plains—waste from the land along the course which the river is unable to bear to the sea over its gentle lower slope.

The Alps as a barrier to the spread of life, and as a refuge from invasion, stand as rugged mountains reaching above the snow line. Their ruggedness is due to their youth and to the fact that denudation, working high above base level, on rocks of very different degrees of hardness, has been able to work rapidly and scar and carve the mountains profoundly. With greater age mountain peaks and ridges are lowered, the valleys are broadened, and the rivers slowly shift position, eating their way backward at the headwaters, robbing weaker opponents of drainage area, and pushing their way across ridge after ridge, as in the Appalachians. The importance of the river gaps to transportation and the influence of mountains on occupation are observable throughout the world.

Rising land gives a straight coast, as along Western South America; sinking forms an irregular coast, with many islands, peninsulas, harbors, and straits, as in the Northeastern United States. A shelving coast of soft materials which has recently assumed its position is skirted by sandbars, like the coast south of New York, while a young coast of hard rock has bold headlands, with beaches in the bays. Here again are innumerable opportunities to study land forms in order to understand their cause and point out their influence on life.

The physiography of the lands investigates islands, peninsulas, capes, plains, plateaus, and valleys; it studies their differences in form; it distinguishes between the different kinds of hills,

cliffs, talus slopes, etc. In fact, it studies all land features, and in all cases it is concerned with the form, its cause, its relation to other land forms, and its effects on life. It shows how, in their conflict, the movements of the crust and the operation of the agents of denudation make land forms by constructional and by destructional processes. It shows that there is a constant building up of land forms by both the internal forces of elevation and the external forces of denudation; and that there is constant tearing down by the forces of denudation. It is the province of physiography to trace the operation of these processes, both to see how they modify the lands and to discover the influences of these modifications on life.

PHYSIOLOGICAL SELECTION. A theoretical explanation proposed by Romanes of the evolution of species on the principle of the prevention of intercrossing. Hence Romanes also referred to the assumed law as that of the "Segregation of the fit." He was led to his generalization by consideration of the facts of sterility between species, and of fertility between varieties and races. Basing upon observation the postulate that the reproductive system was the most susceptible to change of any part of an animal's organization, he argued that in that system would often (perhaps more often than in any other) arise independent variations in individuals. If these were of such a character as to tend toward sterility between them and parent-forms, they would tend to separate the variety from the species and a new species would evolve. Romanes concluded that the principle of sterility between species was essential to the separate existence of species.

PHYSIOLOGY (Lat. *physiologia*, from Gk. *φυσιολογία*, natural philosophy, from *φυσιολόγος*, *physiologos*, discoursing on nature, natural philosopher, from *φύσις*, *physis*, nature + *λόγος*, *logos*, word, account, ratio, from *λέγειν*, *legein*, to say). Under the term physiology, when used in its widest sense, we include all that is known of the properties of living matter. Following the great line of demarcation of living things into animals and plants, we have an animal physiology and a plant physiology. The two subjects, while closely related, are sufficiently different to be considered as separate sciences and to require specialists of different training for their study. In animal physiology we have to deal especially with the properties of animal protoplasm, and although the fundamental properties of this material are believed to be much the same in all animals, yet for each animal or group of animals there are minor distinctions which are due in part to fundamental differences in structure, and in part to the variety in the physiological mechanisms developed in different animals. In what follows an attempt will be made to present briefly an outline of the important facts and principles of human physiology, but it should be remembered that the body of facts included under this designation have been obtained in many, if not in most cases, by direct study and experiment upon lower forms of life, not only upon the mammals most closely related in structure to man, but also upon the simplest organisms which for one reason or another have offered especial opportunities for study.

It is convenient to consider the physiology of the human body under two general heads, namely, the properties of the tissues and the properties or functions of the organs and mechanisms. The human body, like that of other animals, starts as a single cell, the fertilized ovum. During the progress of development this cell multiplies to form an infinite number of cells which gradually become differentiated in structure and segregated into groups that are known as tissues. Each tissue is characterized by its appearance, as seen by the eye or with the aid of a microscope, and also by known differences in chemical composition and reaction. We distinguish in the human body the muscular tissue, the nervous tissue, the epithelial tissue, the gland or secreting tissue, the blood, the connective or supporting tissue, the lymphatic tissue, the tissue forming the red blood corpuscles, and so on. Each tissue is different not only in structure, but in its properties. Along with the differentiation in form there is a specialization in function. Without attempting to describe their microscopic characteristics, a word or two may be said of the more important physiological properties of some of these tissues.

THE MUSCULAR TISSUES. In man, as in the other vertebrates, we distinguish three kinds of muscular tissue: (1) the cross-striped or voluntary muscle which forms the musculature of the body by means of which our voluntary movements are made; (2) the heart-muscle, composing the walls of the heart; and (3) the plain or unstriped muscle which is found in the walls of the hollow viscera, such as the alimentary canal, the blood-vessels, the uterus, the bladder, etc. The common characteristic of these three tissues is the property of contracting. While this property may occur in other tissues, it reaches its greatest development in the muscles. In cross-striped muscles the contraction is always started by a stimulus received through the nerves and originated usually in the brain by an act of the will. The contraction is very rapid. A single stimulus gives a single or simple contraction that occupies less than one-tenth of a second. All of our ordinary voluntary contractions are, however, compound or tetanic, that is, they are composed of a rapid series of simple contractions fused together more or less completely. The rapid series of contractions is due to a series of stimuli or nerve impulses received from the brain through the nerve fibres connecting it with the muscle. In every voluntary movement, therefore, whether short or prolonged, we must imagine to ourselves a series of changes in the nerve cells of the brain, which are propagated along the connecting nerve fibres to the muscle or muscles and there set up a series of contractions so rapid that they become fused into a long lasting contraction or movement.

Plain muscle is characterized by the slowness of its contractions. The tissue as found in different parts of the body varies somewhat in this respect, but in all cases its contractions are very

much slower than in the cross-striped muscle. The plain muscle, moreover, is not under voluntary control; we are not conscious of the movements of the stomach, the blood-vessels, etc. The contractions of these organs are brought about by stimuli conveyed to the muscle through the so-called sympathetic nervous system. The slow and prolonged contractions of plain muscle explain the gentle, long-continued movements of the viscera such as occur in the action of the stomach and intestines in propelling food along their length. Heart-muscle is somewhat intermediate in structure between the plain and the cross-striped varieties. Its contractions are also intermediate in duration, but approach closer to the quick movement of the striped muscle. The predominant characteristic of heart-muscle, however, is its property of making spontaneous rhythmic contractions which are due not to external stimuli received through the nervous system, but to processes arising within itself. To this property is due the rhythmic beat of the heart.

Nervous Tissue. The nervous tissue is found in the brain, the spinal cord, the nerve ganglia of the sympathetic system, and the peripheral nerves or nerve trunks distributed throughout the body. The nerve tissue consists of nerve cells and their processes. The body of the cell lies in the nerve centres, that is, the brain, the spinal cord, and the ganglia, and the typical cell has two kinds of processes, one comparatively short and much branched, known as the dendrites or dendritic processes, the other but little branched and in some cases very long, as much as two or three feet. This latter branch is known as the axis-cylinder process; it may pass out of the nerve centres to be distributed to the other tissues forming the essential part of what we call nerve fibres. It is important, therefore, to bear in mind that nerve fibres are essentially long processes from nerve cells and form the mechanism by which the nerve centres are connected with and influence the activity of the peripheral tissues. Physiologically, the important function of a nerve fibre is to conduct a change or process known as the nerve impulse. This impulse travels along the fibre at a rate of about one hundred feet per second. The nerve fibres fall into two great groups, those that convey impulses from the peripheral tissues to the nerve centres, and those that convey impulses from the centres toward the periphery. The former group compose the afferent or sensory fibres, the latter name being used because in many cases the impulses finally reach the brain and give rise to conscious sensations of various kinds. In many cases, however, the impulses conveyed to the nerve centres by the afferent fibres cause no change in consciousness, but manifest themselves by what we call reflex effects, as, for instance, in the movements of the intestines, the blood-vessels, or the heart. The group of fibres that carry their impulses outward from the centre to the peripheral tissues compose the efferent or motor fibres. If these fibres end in muscles, the effect of their impulses is the production of a muscular contraction; if they end in a gland, they cause a secretion; the nature of the resulting action depending on the kind of tissue with which the nerve fibre is connected. It should be stated that there is no known difference in structure between afferent and efferent nerve fibres. Each, like a telegraph wire, can conduct an impulse in either direction. But just as a telegraph wire with a sending apparatus at one end and a receiver at the other is arranged to conduct messages only in one direction, so the afferent and efferent nerve fibres, by the peculiarities of their end connections, are arranged so that normally they can convey effective impulses only in one direction. What we call a nerve or a nerve trunk consists of many hundreds or thousands of nerve fibres belonging usually to both the afferent and the efferent group. Though combined in one bundle, each fibre is physiologically independent and may act alone or in combination with others in the same trunk. In a muscle, on the contrary, the hundreds or thousands of muscular fibres of which it is composed act usually as a unit, all contracting together when the muscle is in action.

Reflex Actions. A large part of the beautiful adaptation and coördination of the different parts of our bodies is effected by the reflex activities of the nervous system entirely outside our conscious knowledge. The way in which these reflexes are produced is illustrated best by the simple reflex movements that can be obtained from a headless frog. If in such an animal, with its spinal cord intact, one of the toes is gently pinched, the leg will at once be drawn in toward the body. If the skin is stimulated by bits of paper moistened with dilute acetic acid, the leg of the corresponding side will be raised and the piece of paper will be wiped off by a neat movement involving the coördinate activity of a number of muscles. What happens in these cases is that the stimulus applied to the skin irritates the sensory nerve fibres and sends in a stream of nerve impulses to the spinal cord. These impulses are conveyed to the dendrites of certain motor nerve cells and arouse in them fresh impulses which are conducted outward through the efferent nerve fibres to the muscles. The original stimulus, or, more accurately, the nerve impulses to which it gives origin are thus, as it were, reflected in the nerve centres and sent to the peripheral tissues, whence the name of reflex action. Every such reflex involves the activity of at least two groups of nerve cells, one connected with the sensory fibres stimulated and one connected with the efferent fibres going to the muscles. Such reflexes may occur in all parts of the spinal cord and brain. A common reflex in ourselves, for instance, is the winking of the eye when its sensory surfaces are touched. As a rule we limit the term reflex action to those cases in which the element of consciousness is not involved. As a matter of fact, however, all of our conscious processes and mental activities are effected by a similar action of one nerve cell or unit on another, the mechanism in action being essentially similar to, although more complex than, the simple reflexes of the spinal cord. In a mammal as well as in a frog it can be shown that if a part of the spinal cord is severed from its connections with the brain, under such conditions that death does not result at once, the part of the cord below the injury will suffice to effect complex movements upon appropriate stimulation of the skin. To the uninformed such movements usually suggest consciousness, but the evidence of physiology proves conclusively that they are entirely unconscious reflexes.

It should be added that the outgoing impulse in reflex stimulation of the cord or brain may proceed through nerve fibres connected with other

tissues such as the heart-muscle, the plain muscle of the viscera or the glands, and the reflex effect, instead of exhibiting itself as a movement of the limbs, may take the form of a secretion, of a change in the heart beat, or of a constriction or dilatation of the blood-vessels. Owing to the complexity of the connections among the numerous nerve cells in the spinal cord and brain, it is evident that reflex effects may be widespread and very intricate. Certain definite paths or connections are inherited or become acquired during life from repeated use, so that the passage of a sensory nerve impulse that reaches the central nervous system is not haphazard, but for the most part along predetermined paths. The wonderful instincts of the lower animals may be regarded as complicated reflexes, and the unconscious regulation of the different parts of our body, especially the activity of the internal organs or viscera, is controlled in this way by the nervous system.

The Circulatory Mechanism. The anatomical mechanism for the circulation of the blood and lymph consists of the heart, the blood-vessels, and the lymph-vessels. With regard to the blood we have the central fact that the powerful musculature of the heart serves as a force-pump driving the blood out from the ventricles through the circuit of the blood-vessels and back to the heart. The system of arteries branching from the heart resembles a tree with its central trunk and its vast number of branches of different sizes. As one goes outward from the heart toward the periphery, the arteries distributed to each organ become smaller and smaller until they end in minute capillaries. The combined area of these branches increases, however, toward the periphery, so that the sum of the areas of all the capillaries arising from the aorta is several hundred times as great as that of the aorta itself, just as the combined diameters of all of the twigs of a tree would much exceed that of the trunk. The quantity of blood being practically the same at all times, it becomes distributed as it goes out from the heart over a wider and wider area, or, to use a convenient figure, flows through a wider and wider bed. As a result of this fact the velocity of the blood-flow becomes smaller as we approach the capillaries. While in the aorta the blood may flow with a velocity of 300 millimeters per second, in the capillaries the velocity becomes reduced to $\frac{1}{2}$ millimeter. In the venous system the same general fact holds true. The capillaries unite into larger veins, and these into still larger ones, until finally all of the blood in the aortic system is collected into two large veins, the superior and the inferior vena cava, which open into the auricles. As a consequence the blood, as it flows back to the heart, passes through a path that becomes narrower and narrower, and its velocity increases proportionately. With regard to the velocity of the blood-flow, therefore, we can state that it is greatest in the large arteries and veins and least in the capillaries.

In the arteries, moreover, the blood is under a much greater pressure than in the capillaries and veins. From a cut artery the blood spurts to some distance, while from a cut vein the blood flows out quickly, but with little force. The cause of this difference is easily understood. In flowing through the vessels the blood encounters considerable resistance. Naturally this resistance is greatest in the capillaries and in the small arteries and veins communicating with them. On account of the great resistance in the capillary region, known technically as the peripheral resistance, the blood is dammed up, retarded on the arterial side, stretching the elastic walls of the arteries and putting the blood under a considerable tension. In the capillaries the pressure of the blood is much less, and in the veins it becomes smaller and smaller as we approach the heart. Physiologically the most important part of the blood-circuit is in the capillaries. While flowing through these thin-walled and very minute vessels the blood fulfills its function of nourishing the tissues. At this point the blood, while still under some pressure, is flowing at its slowest rate, and the liquid part of it, the blood plasma, transudes through the thin walls and comes into direct contact with the tissues, thus forming the tissue-lymph. The oxygen carried by the red corpuscles of the blood is liberated in the capillaries and diffuses from the blood to the tissues, being transported to the latter while held in solution in the lymph. The lymph gives up its food materials and oxygen to the tissue cells and at the same time receives from them the waste products and carbon dioxide formed during their nutritive activity. The lymph is prevented from accumulating in the tissues by the fact that it is continually drained off by the system of lymphatic vessels. These vessels form a system parallel in course and structure to that of the veins. They begin in the tissues by small capillaries which unite to larger and larger vessels, forming eventually two main trunks that open into the veins of the neck. By this arrangement the excess of lymph is continually drained off and returned to the blood. The means by which the supply of lymph is regulated forms one of the most interesting and difficult subjects of study in modern physiology.

The heart and blood-vessels are not a fixed and rigid system. On the contrary, they are supplied with nerves through which the beat of the heart and the capacity and resistance of the blood-vessels may be reflexly adapted to the different conditions of the body as a whole, or the individual needs of its separate parts. The heart receives two sets of nerve fibres; one, the inhibitory fibres, are capable of slowing the heart-beat; the other, the accelerative fibres, quicken the rate. The small arteries, on the other hand, receive also two sets of nerve fibres; one, the vaso-constrictors, causes a diminution in size of the blood-vessels, while the other, the vaso-dilators, brings about an increase in size. The numerous conditions under which these regulating nerve fibres act are too complex to be described here. The mechanism is so adjusted as to control automatically the supply of blood to different organs under varying conditions of rest and activity.

The Respiratory Mechanism. In mammals like ourselves the chief organ of external respiration is the lungs. When the inspiratory muscles are contracted the chest is enlarged and air flows into the lungs. When the expiratory muscles are contracted the chest is diminished in size and air is forced out of the lungs. In ordinary respiration the expiratory act is entirely passive; the chest, expanded by the action of the inspiratory muscles, sinks back into its normal position when these muscles cease to act. In forced breathing,

however, the expiratory muscles come into action. By means of these respiratory movements the air in the lungs is continually renewed, the supply of oxygen is maintained, and the carbon dioxide is removed. The oxygen contained in the air sacs of the lungs diffuses through their thin walls, and, coming into contact with the blood, it unites chemically with the coloring matter of the red corpuscles, the hæmoglobin. In this combination it is carried to the heart, and thence distributed over the body through the various arteries. When the blood reaches the capillaries the compound of hæmoglobin and oxygen is broken or dissociated by the physical conditions there prevailing, while the liberated oxygen passes into solution in the blood plasma and lymph, and is thus conveyed to the tissues. On the other hand, the general nutritive change or metabolism of the tissues results in the formation among other things of carbon dioxide. This substance is a waste product, and if it accumulates in the tissues, brings on a suppression or perversion of the normal nutritive processes. Under normal conditions, however, it is rapidly removed by the lymph and blood. As the oxygen passes from the blood to the tissues by diffusion through the thin-walled capillaries, so the carbon dioxide as rapidly as it is formed streams in the opposite direction from tissues to blood. Each gas follows the physical law of diffusion from a point of greater to one of less tension. Within the blood the carbon dioxide is held mainly in chemical combination, partly with the proteids of the blood plasma, partly with the proteids of the blood corpuscles. When the blood reaches the lungs this loose chemical union breaks down, the carbon dioxide is liberated and diffuses into the air-sacs of the lungs, whence it is given off in the expired air. The process of respiration, therefore, may be divided into two parts, external and internal respiration. Under the former term we include all the processes involved in the movement of air into and out of the lungs, and the exchange of oxygen and carbon dioxide between the blood and the air in the lungs. By internal respiration we mean the exchange of oxygen and carbon dioxide between the tissues and the blood as well as the processes of nutrition by means of which the oxygen is used and the carbon dioxide produced. What we call arterial blood differs from venous blood in that it contains more oxygen and less carbon dioxide, and to this difference in the gaseous contents is due also the well-known variation in color, arterial blood having a scarlet tint, while the venous blood is purplish or crimson. The machinery for the movements of respiration, that is, the respiratory muscles, are under the control of the central nervous system. These muscles may be influenced within certain limits by direct voluntary effort; but a far more important factor is their unconscious or reflex regulation exerted through the respiratory nerve cells or nerve centre found in the medulla oblongata. By the activity of this centre the respiratory movements are kept continually in play and the extent of the respirations is adjusted to the needs of the body.

Digestion and Nutrition. The living matter of the animal body is characterized, as compared with plant protoplasm, by its limited powers of assimilation. While the latter can construct living matter from comparatively simple inorganic material, such as carbon dioxide, water, and nitrogen containing salts, the former requires food in the more complex form of organic material. Since in the last analysis this organic food is derived from the plant kingdom, it may be said that the maintenance of animal life is only possible through the synthetic activity of plant protoplasm. All of our varied foods are found upon analysis to be composed of essentially the same materials united in different proportions. These constituent materials of our foods are known as food-stuffs and are usually classified as *proteids*, *fats*, *carbohydrates*, *water*, and *salts*. Of these substances the water, inorganic salts, and proteids are absolutely essential. The two former are necessary to the composition and reactions of the living tissues, but they do not directly furnish any energy to the body. The requisite amount of water is controlled by the sensation of thirst, and the proper proportions of the inorganic salts are provided in our foods without the necessity of any conscious selection on our part, except perhaps in the case of sodium chloride. Proteid foods have a different value. They are complex nitrogen-containing compounds which in the body are destroyed and reduced to much simpler substances, namely, carbon dioxide, water, and urea. This destruction of proteid is essentially an oxidation, and as much heat is given off in the process as would be liberated outside the body by burning proteid to the same end-products. Proteids are an absolutely necessary constituent of food, because they contain nitrogen in a form capable of being used in the construction of living matter. Fats and carbohydrates, since they contain no nitrogen, cannot be used alone in the synthesis of protoplasm. They are nevertheless valuable foods, since they are readily destroyed or burned in the body with the liberation of energy in the form of heat or muscular work. In a normal diet proteids, fats, and carbohydrates are usually combined in certain proportions, and experience as well as direct physiological experiments show that within limits the fats and the carbohydrates may be interchanged, and furthermore the greater the amount of these two substances used the less will be the amount of proteid required; or as we say in physiology, fats and carbohydrates are 'proteid-sparers.'

The nutritive history of these three energy-yielding foods may be summarized briefly as follows: The proteids in whatever form they may be taken are digested partly in the stomach by the action of the gastric juice and partly in the intestines by the action of the pancreatic juice. By the act of digestion the food proteids are converted into simpler and more soluble forms known as peptones and protoses, which are then absorbed into the blood and carried to the various tissues. Here they are utilized in part to form protoplasm, either to replace that broken down in metabolism or to supply material for growth. But much the larger part of the proteid is simply destroyed in the tissues with the transformation of some of its chemical energy into a corresponding amount of heat. The fats are prepared for digestion in the stomach, but undergo the important change that fits them for absorption after they are brought into contact with the pancreatic juice in the small intestine. After absorption they are found in the blood and lymph for a time, but soon pass into the tissues. Here they may be deposited as part of our normal store of

body-fat, but with the usual diet of adult life they are supposed to be completely burned. It is known from experiments that one gram of fat burned outside or inside the body yields as much heat as 2.2 grams of proteid. The carbohydrates include the starches and the sugars which from a nutritive standpoint have the same value. The starches form the bulk of our diet, and they are digested partly in the mouth by the action of the saliva, but mainly in the small intestine by the action of the pancreatic secretion. Under the influence of these secretions the starches are converted into a form of sugar, which is then absorbed into the blood. As the blood from the intestines passes through the liver this absorbed sugar is removed and again converted into a form of starch known as glycogen, which is deposited or stored in the liver cells. From time to time the glycogen is reconverted to sugar and given off to the blood. The regulating mechanism controlling this production and conversion of glycogen is so adjusted that under the normal conditions of life the blood always contains a nearly constant amount of sugar. Sugar, therefore, is the final form in which all of our carbohydrate food is brought to the tissues—and under the influence of the living matter it is eventually oxidized to carbon dioxide and water. In the long run, therefore, the final fate of our food is to be burned and furnish energy in the form of heat, muscular work, etc. The continual consumption of food is necessary to maintain the body temperature, and in the body we have very complex regulating mechanisms which control the loss of heat and to a certain extent its production, with the normal result that the temperature of the body remains nearly constant under all the varying conditions of life. It has been shown with scientific accuracy that all the detectible energy given off from the body is derived directly from the food consumed. The energy value of any food can, therefore, be determined by ascertaining the amount of heat produced by burning it, or more conveniently by ascertaining the heat value of proteids, fats, and carbohydrates, and then analyzing the food to determine how much of these three foodstuffs is contained in it.

The Central Nervous System. Some statements regarding the structure of the nervous system will be found in the beginning of this article. (Consult also the article on Nervous System and Brain.) At the base of the brain immediately adjoining the spinal cord we have the medulla oblongata. In this part of the brain are found certain important collections of nerve cells which control the movements of respiration, of the heart, and of the blood-vessels, their activity being entirely unconscious and under the influence of reflex stimulation. Collections of nerve cells connected with and regulating the action of physiological mechanisms are known as nerve centres, and in the medulla we recognize the existence of the three centres mentioned and designate them as the respiratory centre, the cardio-inhibitory centre, and the vaso-motor centre. They and other similar centres regulate the activity of the visceral organs, whose functions are discharged for the most part without our conscious knowledge or control. Injury to the medulla or severance of its connections with the spinal cord is fatal at once, owing to the destruction of the connections of the respiratory centre with the respiratory muscles and the consequent inability to breathe. In the cerebellum we have an organ which seems to control the coördinated activity of the voluntary muscles. Extensive injury to the cerebellum, while not accompanied by actual paralysis, renders the animal incapable of executing orderly movements. If the animal survives the injury, the ability to make coördinated movements may be recovered more or less completely, but some awkwardness and muscular weakness persist as permanent results. In the nerve cells of the cerebral hemispheres we have the seat of the conscious sensations and of all the so-called psychic activities. Modern physiology has shown that different parts of the cerebral hemispheres have different functions. The optic nerve fibres end eventually in the occipital lobes, and here our conscious sensations of vision are mediated. A similar arrangement prevails for the other senses. In the cortex of gray matter covering the cerebral hemispheres there are in fact certain sense areas each of which mediates a different kind of consciousness. Other areas are connected with the various muscles of the body and form the centres through which our voluntary movements are executed, while in still other regions we have areas in which are stored the memories of past experiences and in which the factors of sensation are organized into the complex associations that characterize our mental life. Injuries to the brain may, therefore, be followed by quite different results according to the region involved. There may be a paralysis of this or that group of muscles, a loss of this or that primary sensation, or a disturbance or perversion of this or that group of memory associations. The so-called aphasias form noteworthy illustrations of these facts. Injury to certain limited areas of the brain may result in a partial or complete loss of the power of speech, or of the ability to understand either written or spoken language without any interference with vision or hearing. When defects of this character exist it is possible to locate the probable seat of the lesion, and not infrequently this knowledge has been made the basis of successful surgical operations.

History of Physiology. The history of physiology is coextensive with that of medicine. Its relatively slow advancement through many centuries was closely associated with the growth of anatomical, chemical, and physical knowledge. In modern times, however, dating perhaps from the first part of the nineteenth century, physiology has become an independent science with a technique peculiarly its own, yet adopting more and more the exact methods that have arisen in the sciences of physics and chemistry. This development of physiology has been especially marked since investigators abandoned the idea of a special vital force controlling the phenomena of life and set themselves to the task of explaining the properties of living matter in terms of the forms of energy recognized as responsible for the phenomena of inanimate nature. The great facts in physiology, as in other subjects, have been discovered in a few cases only by the genius of individual workers. In most instances they have developed gradually as the result of the combined labors of many investigators, so that a history of the growth of the fundamental principles of modern physiology involves a discussion of the progress of the natural sciences in gen-

eral. Every important advance in physics and chemistry has influenced and will continue to influence the development of physiological knowledge. Some of the significant discoveries that belong especially to physiology and that can be traced more or less exactly to a definite period and individual observers are as follows: The circulation of the blood (Harvey, 1616-28); the existence of the lymphatic system of vessels (Aselli, 1622); the microscopic structure of the lungs, capillaries, glands, and other tissues (Malpighi, 1660-90); the discovery of the mammalian spermatozoön (Leeuwenhoek, 1678); the method of direct measurement of blood-pressure (Hales, 1732); the independent irritability of muscle (Haller, 1757); the discovery of oxygen and its functions in respiration (Lavoisier, 1775); the digestive action of gastric juice (Réaumur, 1752); the distinction between motor and sensory nerve fibres (Bell and Magendie, 1811-22); the discovery of the mammalian ovum (Von Baer, 1827); the true nature of the secretions of glands (Johannes Müller, 1830); the existence of enzymes, unorganized ferments, in the gland secretions and saliva—diastase (Leuchs, 1831); pepsin (Schwann, 1836); the nature of reflex actions (Marshall Hall, 1837); the electrical phenomena of muscle and nerve (Du Bois-Reymond, 1843); the existence of inhibition and inhibitory nerve fibres (Weber, 1845); the introduction of the graphic method in physiological experimentation (Ludwig, 1847); the existence of secretory nerve fibres (Ludwig, 1851); the existence of vaso-motor nerve fibres (Bernard, 1851); the existence and functions of glycogen (Bernard, 1857); the function of hæmoglobin in respiration (Hoppe-Seyler and Stokes, 1862-64); the localization of function in the cerebrum (Fritsch and Hitzig, 1870); the establishment of the fact of internal secretions (Brown-Séquard and others, 1891). For full information, consult: Foster, *Text-Book on Physiology* (Philadelphia, 1885); *The American Text-Book of Physiology* (2d ed., ib., 1900); Schäfer, *Text-Book of Physiology* (New York, 1900). For details of the histological features, consult Piersol, *A Text-Book of Normal Histology* (Philadelphia, 1901).

PHYSIOLOGY OF PLANTS. History. Up to the close of the seventeenth century nothing was known of the physiology of plants beyond the scattered impressions derived from the practical cultivation of plants in fields and gardens. Inasmuch as the physiology of animals was better known, the first study of the actions of plants was an endeavor to identify plant functions with those of animals. As the functions of animals were only superficially known, this attempted identification led oftentimes to most egregious errors. But as the nature of animal functions became better known, the essential identity of the processes in both sorts of living beings became more evident. At first the study of physiology was scarcely more than an enumeration of plant activities and their comparison with those of animals. Later, however, [illegible] were made to investigate the causes and conditions of the functions. For this a knowledge of [illegible] was recognized as of prime importance. Deeper insight into physiology, however, [illegible] knowledge of physics and chemistry; [illegible] only when these two sciences under[illegible] progress found transformation and extension that explanations of plant phenomena began to be possible. Among the earliest investigations after the revival of learning were those made in Italy by Malpighi on the movement of sap, and those of Ray on the influence of light upon the colors of plants. About the same time in Germany Camerarius proved the necessity of pollen for the formation of fertile seeds.

Early in the eighteenth century Hales published his studies on the movement of sap and the evaporation of water from the leaves. Later in the eighteenth century came the investigations of Koelreuter, who added to the knowledge of sexuality in plants by his experiments on hybridization. It was in connection with these experiments that the relations of insects to pollination were first pointed out. Later (1793) these interesting relations were set forth at length by Christian Konrad Sprengel, whose famous "Das entdeckte Geheimnis der Natur" was scarcely appreciated until the contributions of Darwin had opened the eyes and understanding of naturalists to Sprengel's extraordinary work. About the same time Ingenhouss showed that the green parts of plants when illuminated absorb carbon dioxide and eliminate oxygen, thus deriving the carbon which they need from the atmosphere. He also showed that the living parts of plants absorb oxygen, whether illuminated or not, and evolve carbon dioxide, thus establishing the fundamental facts of nutrition and respiration. This work was further confirmed by Senebier, who demonstrated that the decomposition of carbon dioxide takes place only in green organs. He also studied the influence of light upon the growth and green color of plants. By the beginning of the nineteenth century Nicolas Théodore de Saussure had shown that plants not only fix carbon from carbon dioxide, but also use the elements of water, which, with the mineral salts, are a necessary part of the food materials. Between 1822 and 1832 De Saussure and Goeppert established the connection between the respiration of plants and the development of heat in their bodies. Through the influence of Liebig, about the middle of the century, Ingenhouss's clear exposition of the respiration of plants, which had been fairly established, was discarded, to be reinstated in confidence only after 1860 by the father of modern vegetable physiology, Julius von Sachs. Yet Liebig's valuable work in connection with the chemistry of foods and food materials of plants and Boussingault's investigations in France, especially in relating the known facts to the empirical processes of agriculture, were of great service to both cultivators and physiologists. The year 1860 marks the rise of modern physiology, as indeed it does the rise of modern biology, many cooperating causes, the most notable of which was the publication of Darwin's *Origin of Species*, furnishing the impulse to renewed investigation.

Scope. As a science, plant physiology concerns itself with every inquiry relating to the functions and behavior of living plants. Certain aspects of physiology, namely the relation of living plants to the environment, physical (including soil, water supply, temperature, etc.) and biological (i.e. other plants and animals), have recently been separated from physiology proper and named ecology (q.v.). Physiology proper restricts itself to the activities of the individual

plant. Its study demands a previous knowledge of the anatomy (q.v.) and histology (q.v.) of plants, since familiarity with plant mechanism must precede the knowledge of plant function.

The functions of plants may be divided for convenience into certain groups. *First*, processes connected with the absorption of materials by the plant from the surrounding medium. Everything which enters the plant body must do so in solution. The plant depends, therefore, fundamentally upon water, which, with an infinite variety of solutes, both solid and gaseous, it absorbs. (See ABSORPTION.) *Second*, processes by which materials escape from the plant body. Gases, especially carbon dioxide and oxygen, are evolved (see AËRATION; OSMOSIS); a great variety of materials are eliminated from the plant body by various processes of secretion (q.v.); and water is evaporated in great quantity by the surfaces of land plants. (See TRANSPIRATION.) *Third*, processes by which water and foods are moved about from the points of absorption or manufacture to the points of use, storage, or loss. But in spite of the fact that the movement of water was almost the first subject that attracted the attention of observers, no satisfactory explanation has yet been devised. (See CONDUCTION.) *Fourth*, processes of nutrition. Carbohydrate foods are made only by green plants under the influence of light, a power which is of the utmost importance, since the commercial supply of food and energy depends at present almost wholly upon green plants. The making of carbohydrates is fully described in the article PHOTOSYNTHESIS. (See CHLOROPHYLL; CHLOROPLASTS.) All plants, however, make proteid foods, when the necessary supply of carbohydrates, nitrates, and salts is furnished. Proteid synthesis is discussed in the article FOOD OF PLANTS. When proteid foods are at hand, either through manufacture or absorption, they undergo various changes before they become a part of the protoplasm. (For what little is known of these processes, see ASSIMILATION.) *Fifth*, processes concerned with the release of energy in the plant body or adjacent to it, in such a way that the kinetic energy can be applied to such work as the plant must do. For most plants, these processes constitute respiration. (See RESPIRATION IN PLANTS.) For a few plants fermentation (q.v.) seems to replace, in part at least, the normal respiration. *Sixth*, processes of repair and growth. One of the important activities of the plant is the formation of new material or the rearrangement of old into new parts. The diverse operations involved in this constitute growth (q.v.). *Seventh*, processes of perception and response. Every function of the plant is more or less influenced by the changes occurring in its vicinity, whether these be entirely outside of the body or only in adjacent parts. In order to adjust itself to these changes the plant must receive impressions of them, and these impressions must result in appropriate adjustment. The changes in the protoplasm corresponding to changes in the surrounding medium and the chain of effects thus initiated, are said to manifest irritability (q.v.). The visible alterations of the rate of growth (q.v.) or in movement (q.v.) are most striking evidences of irritability. See CHEMOTROPISM; GEOTROPISM; HELIOTROPISM; HYDROTROPISM; MOTOR ORGAN; RHEOTROPISM; STIMULUS; TENDRIL; TRAUMATROPISM.

A brief and elementary summary of plant physiology will be found in Barnes, *Plant Life* (New York, 1898).

PHY'SODON (Neo-Lat., from Gk. *φύσα*, *physa*, bellows, breath, bubble + *ὀδούς*, *odous*, tooth). An extinct sperm whale known by its skull, found in the Miocene formations of Patagonia. It differed from the modern sperm whale in having enamel-capped teeth in its upper jaws. See CETACEA.

PHYSOSTIG'MA. See CALABAR BEAN.

PHYTOGEOGRAPHY. See DISTRIBUTION OF PLANTS.

PHYTOLAC'CA (Neo-Lat., from Gk. *φυτόν*, *phyton*, plant + Neo-Lat. *lacca*, lac, from Per. *lak*, *luk*, Hind. *lākh*, from Skt. *lākṣā*, lac-insect, from *lākṣā*, hundred thousand, referring to the numbers of insects in each nest; so called from the crimson juice of the berries). A genus of about 20 species of dicotyledonous herbs and half-shrubs of the natural order Phytolaccaceæ, natives of warm parts of Asia, Africa, and America. *Phytolacca decandra*, the poke or pocan, a native of North America, now naturalized in some parts of South Europe, is occasionally cultivated for its young shoots, which are eaten like asparagus. The juice of the berries, which are about the size and color of black currants, is employed in the adulteration of wine. The young shoots of *Phytolacca acinosa* are boiled and eaten in the Himalayas. Under the name *Phytolacca esculenta* it has been introduced into gardens.

PHYTOLACCA (in medicine). Official under either of two forms, the fruit or the root of *Phytolacca decandra* or poke, also called 'pigeon-berry' and 'garget root.' The fruit is a small, deep purple compound berry, nearly round, with a sweet and slightly astringent taste. The root is "large, branched, fracture fibrous, inodorous, sweetish, and acrid" (Potter). A fluid extract and a tincture are the preparations used, besides the berry and root. Poke has been used in ulcers, certain tumors, eczema, sycosis, and other skin diseases, chronic rheumatism, mastitis, tonsillitis, and pharyngitis. It has been used to decrease adipose tissue and thus reduce obesity since 1858. When given in large doses, phytolacca causes nausea, depression, vomiting, and purging. It lowers the rate of respiration and weakens the heart's action, and has caused convulsions. See POKE and Colored Plate of POISONOUS PLANTS.

PIACENZA, pē'ä-chēn'tsä. The capital of the Province of Piacenza, Italy, situated on the right

bank of the Po [illegible] miles [illegible] its confluence with the Trebbia, 13 miles southeast of Milan (Map, Italy, D 2). The city is gloomy and desolate in appearance, though its thoroughfares are broad and regular. The Stradone is one of the most beautiful streets in Italy. Piacenza occupies a position of great strategic importance, and is fortified with solid walls and a strong castle. The Italian Government has strengthened and extended these fortifications by the construction of external defensive works, and by a formidable intrenched camp. The city has numerous fine palaces and churches. The attractive cathedral, an edifice in the Lombard Romanesque style, founded in the eleventh century, is interesting for the grotesque character of its interior decorations. It has frescoes by Guercino and L. Carracci. The Church of Sant' Antonino, the original Cathedral of Piacenza, has been several times rebuilt. Santa Maria di Campagna has excellent mural paintings by Pordenone. The noteworthy San Sisto, an ancient church rebuilt in the Renaissance, gave its name to Raphael's Sistine Madonna. Among the other principal buildings are the immense Palazzo Farnese, begun in 1558 and never completed, once famous, but now serving as barracks; the fine Palazzo Municipale, dating from the thirteenth century, with its arched arcades and pinnacles; and the Palazzo dei Tribunali with curious courts, now in ruins. The principal square is the Piazza de' Cavalli, so called from the colossal bronze equestrian statues of the Dukes Alessandro and Ranuccio Farnese. There are a public library with over 130,000 volumes, a splendid theatre built in 1803, two new theatres, several hospitals, and an arsenal. Piacenza has manufactures of silk, cotton and woolen goods, hats, pottery, and machinery, and a trade in wine, grain, cheese, and marble from its quarries. Population (commune), in 1881, 31,987; in 1901, 36,064.

Piacenza, the ancient Placentia, was founded by the Romans in B.C. 219. In B.C. 200 it was plundered and burned by the Gauls, but recovered its prosperity with the construction of the Æmilian military road, which had its western terminus here. In the twelfth century it became a member of the Lombard League. In 1545 Piacenza, along with Parma, was erected into a duchy for the Farnese family. (See PARMA.) An important battle occurred here in 1746 in which the allied French and Spaniards were defeated by the Austrians. Consult Giarelli, *Storia di Piacenza* (Piacenza, 1889).

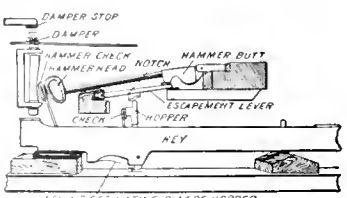
PIA MATER. See NERVOUS SYSTEM AND BRAIN.

PIAN'KISHAW. An Algonquian tribe, originally a band of the Miami, formerly residing chiefly upon the lower Wabash and claiming jurisdiction over most of southern Indiana and southeastern Illinois. When first known to the French, about 1670, they were in central Illinois, with the Miami and Illinois, and probably reached the Wabash about 1700. In 1832 they and the Wea sold all their claims in the east and agreed to remove to Kansas as one tribe. In 1867, having in the meantime consolidated with the remnants of the Illinois, they removed to the Indian Territory. They probably never numbered many more than 1000. In 1870 they were reported at 950, in 1895 at 800. In 1825 there were only 234 remaining in their original country, with a few others residing in Missouri. The whole body of mixed-blood Piankishaw, Wea, Kaskaskia, and Peoria together now number only 180.

PIANO (It., soft), abbreviated *p.* A sign used in music to denote that the strain where the indication occurs is to be played with less than the average intensity of force: *pp*, or *ppp*, for *pianissimo*, signifies very soft, or as soft as possible. *Piano* is used in contradistinction to *forte* (q.v.), and the transition from the former to the latter is indicated by the sign $<$; the change from *forte* to *piano* is marked by the opposite sign $>$.

PIANOFORTE (It. *pianoforte*, from *piano*, soft + *forte*, loud). A percussive instrument consisting of wire strings struck by felt-covered hammers, operated by keys arranged in a keyboard. It was directly evolved from the clavichord and harpsichord (qq.v.). The history of the pianoforte proper begins with the year 1709. Scipione Maffei in the *Giornale dei letterati d'Italia* (1711) gives a detailed account of four instruments built by Bartolommeo Cristofori (not Cristofali, as generally stated until quite recently), named by him *pianoforte* and exhibited in 1709. The earlier clavichord and harpsichord admitted no gradation of the loudness of tone. In order to render musical performances more expressive by a contrast of soft and loud tones, three different men about the same time turned their attention to this matter. These were the just-mentioned Cristofori in Italy, Marius in France, and Schröter in Germany. Marius exhibited some harpsichords with hammer-action in Paris in 1716, but it is not known that Schröter ever built an instrument or had one built for him. Schröter claimed to have invented the hammer-action between 1717 and 1721. But not until 1738, when Cristofori's instruments had become famous, did he come forward with his claim; and he waited even till 1763 before he published for the first time a drawing of his invention.

Cristofori's earlier instruments show a very simple form of escapement; the return of the hopper to a perpendicular position is secured by means of a spring. But there is no check to prevent the rebound of the hammer after striking

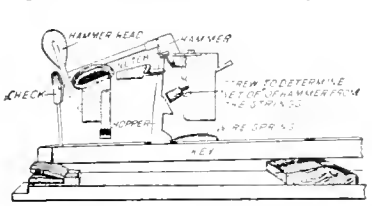


ACTION OF CRISTOFORI'S PIANO.

the string. Two later instruments, built in 1720 and 1726 respectively, have a device for checking. In order to withstand the force of the impact of the hammer it was necessary to use thicker wire than in the harpsichord. This thicker wire increased the force of the tension, and necessitated a strengthening of the supporting framework. The hammers were covered with leather, and every key had a damper. Thus the fundamental principles of our modern grand pianos are all found, though in a simpler form, in the instruments of Cristofori. The compass of these instruments was four to four and a half octaves. The action of

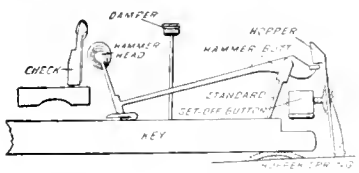
Cristofori was adopted in its essential features by the famous organ-builder Silbermann. His first instruments failed to win the approbation of J. S. Bach, who criticised them for their weak treble and heavy action. This led Silbermann to spend some years in experiments which finally resulted in success.

Up to 1760 all pianofortes were built in the shape of the modern grand. In that year Zumpe a German workman, settled in London and began to build instruments in the square form, which at once became very popular. About the same time other makers settled in London and practically made the English capital the centre of the world's pianoforte trade. About 1790 Broadwood, working upon acoustic principles, discovered the fact that when struck at a certain point the string would yield a fuller tone. Accordingly he adjusted the hammers so as to obtain this result. He also transferred the wrest-plank (the block in which the tuning pins are held) to the back of the case, and in 1783 invented the pedals: one by means of which all the dampers could be raised, the other to soften the tone by dropping a piece of cloth over the strings. In these improvements Broadwood had the advice and assistance of Backer and Stodard. The action as perfected by Broadwood has come to be known as the English action, and is generally in use today.



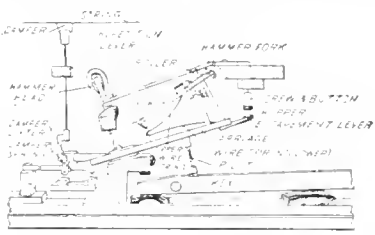
ENGLISH GRAND PIANOFORTE ACTION.

Meanwhile German manufacturers had not been idle. Stein, a pupil of Silbermann, invented a new action, which has become famous as the Viennese action. While in Cristofori's (English) action the axis of the hammer does not change, because the hammer is fixed upon a lever separate from the key, Stein attached the hammer directly to the rear end of the key itself, causing a change of axis of the hammer when the key is struck. This produced the extreme lightness characteristic of the Viennese action. Stein's



STREICHER'S GRAND PIANOFORTE ACTION.

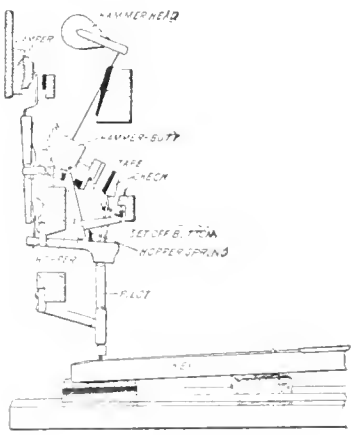
son-in-law, Streicher, in 1794 further improved this action and established a great reputation for his instruments. France was supplied chiefly with English pianos until Erard (a German whose name originally was Erhardt) settled in Paris in 1777. The Revolution drove him to London, where he made himself thoroughly familiar with English methods. Even after his return to Paris Erard continued to use the English action, but meanwhile he was seeking some improvement. His experiments resulted in 1821 in the double escapement action, which soon spread the fame of Erard all over the world. The next important manufacturer in France was again a native German, Pape, of Hanover. Pape invented, in 1827, a down-striking action where the action is above



FRENCH GRAND PIANOFORTE ACTION.

the strings. He also substituted felt for leather in the covering of the hammers (1839). But this departure had already been made a few years previous by Babcock, of Boston.

In order to save space, some English makers toward the end of the eighteenth century conceived the idea of building pianos in an upright form. The first attempts consisted in nothing more than turning a grand or square instrument on one side. The first genuine upright was patented (1800) in England and the United States by John Isaac Hawkins, an Englishman living in the latter country. It is remarkable for containing most of the features which distinguish the modern upright. In the direct line of piano development, however, we owe a greater debt of gratitude to Southwell, who after fourteen years of experimenting exhibited the first upright piano that yielded practical results in 1807. This he called the 'Cabinet.' In 1811 he built another instrument which shows many decided improvements. Wornum still further improved this



ENGLISH UPRIGHT PIANOFORTE ACTION.

model by the introduction of diagonal stringing. The increased length of the strings yielded a more powerful tone. He also invented a new action principle (the so-called lever-check action), which was taken up and further improved by Pleyel of Paris, in which form it became known as the French action.

It must not be imagined that the pianoforte immediately upon its appearance at the beginning

of the eighteenth century superseded the harpsichord or clavicembalo. These instruments continued to be made; especially the clavicembalo kept its position in the orchestra throughout the century. Composers still wrote for the harpsichord. The earliest known composition written especially for pianoforte appeared in 1771. The composer, a certain Müthel, entitles it "Duetto für zwey Claviere, zwey Fortepiano oder zwey Flügel." But the technique is not different from that of the harpsichord. The first compositions written especially for the pianoforte and showing a technique characteristic of the new instrument are three sonatas (op. 2) by Muzio Clementi, published in 1773. From that time on composers began to study the peculiarities of the pianoforte and to employ the proper technique. The colossal pianoforte works of Beethoven were destined to revolutionize the manufacture of pianofortes. Many of his pianoforte works were beyond the capabilities of the instrument at that time. Thus he gave a powerful stimulus to piano-builders to increase both the compass and power of the pianoforte. In order to obtain power of tone the *thickness* of the strings had to be increased; to extend the scale the *number* of strings had to be increased. Manufacturers had to devise some frame capable of withstanding this enormous increase of tension. This led to the use of metal. In 1820 Allen and Thom patented a frame consisting of hollow metal tubes with brass and iron plates supported by heavy wooden crossbars. This was soon adopted by the leading manufacturers. Babcock of Boston in 1825 tried a cast-iron frame, and in 1832 Allen produced a frame that combined the string-plate, tension bars, and wrest-plank in one casting. This was still further improved by Chickering in 1837. In 1859 Steinway & Sons of New York added to the metal frame in one casting an agraffe, which is a small metallic support for the string, inserted between the bridge and the string for the purpose of preventing vibration in that part of the string. The same firm introduced also a double overstrung scale, which is obtained by dividing the strings into two sets, so that one set lies diagonally across the other.

Besides the improvements mentioned innumerable others have been and are still being made. From the four-octave instrument of Cristofori with a moderate tension, supported by a wooden sounding board, the modern pianoforte has developed into an instrument of tremendous tone-power with a compass of over seven octaves and a tension amounting to several tons. A modern pianoforte consists of the following parts: (1) The *frame*, now almost universally made of iron cast in a single piece. At the rear end is attached the *string plate*, into which the strings are fastened. In the front there is the *wrest-plank*, into which the *tuning-pins* are set. Around these is wound the other end of the string, and by turning these pins the tension of the strings is regulated. (2) The *sounding-board*, a thin piece of wood placed under the strings for the purpose of reinforcing the tone by means of sympathetic vibration. (3) The *strings*, made of steel wire, increasing in length and thickness from the treble to the bass. The lower ones are made heavier by being *overspun*, i.e. wound around with a coil of thin copper wire. For the very lowest tones only one wire is used (A–F♯). Then two strings for each tone (G_2–C); above that three strings. (4) The *action*, the entire mechanism required for propelling the hammers against the strings. This includes the keyboard, a row of keys manipulated by the fingers. The keys corresponding to the natural tones are made of ivory, those corresponding to the chromatically altered tones, of ebony. When a key is pressed down the rear end rises and lifts a rod, called *jack*, which, in turn, throws the *hammer* against the string or strings. At the same time a *damper* is raised. The hammer, having struck the string, falls back immediately and is caught by a *check*, preventing a rebound. But as long as the key is pressed down the damper remains raised and thus allows the string to vibrate freely. (5) The *pedals*, levers pressed down by the feet. (a) The *forte* or *loud* pedal raises all the dampers, so that all the strings struck continue to vibrate even after the keys are released. (b) The *soft* pedal, which either throws all the hammers nearer to the strings, so that the striking distance is diminished by one-half, or shifts the hammers a little to one side, so that only a single string instead of the two or three is struck. (c) Some pianos have a third or *sustaining* pedal which does not raise *all* the dampers, but keeps raised only such as are raised by the keys at the moment this pedal is applied. (d) Recently many upright pianos have been built in which the application of a pedal interposes a strip of felt between the hammers and strings, so that only a very faint sound is produced. This is a great convenience while practicing. (6) The *case*. According to the shape of the case, pianos are classified as grand, square, and upright. The square form is no longer built, although many instruments of that shape are still in use. For use in private homes they have been entirely superseded by the uprights, which latter take up far less room. The grand pianos are built in various sizes, from the full concert grand, 8 feet 10 inches long, to the parlor or baby grand, 6 feet long. The cases are often very elaborately carved or even inlaid. There have been special instruments made that cost $50,000.

For the sake of completeness, it is necessary to speak briefly about some inventions made in connection with the pianoforte. There is a device for increasing the volume of tone. This is the *æolian attachment*, an arrangement by means of which a current of air is directed against the strings, reinforcing the vibrations and thus causing a considerable increase in the volume and duration of the tone. In 1891 Dr. Eisenmann, of Berlin, invented the *electric piano*. Besides the ordinary hammer-action this instrument has an electro-magnet attached to each string. By pressing down the keys an electric circuit is closed, and the action of the electro-magnets causes a steady vibration of the strings. When the electric action is employed alone, the tone of the piano closely resembles that of the stringed instruments. By means of a special pedal any tone or chord can be sustained at will even after the fingers have left the keys. The electric action of the hammer-action may be employed each separately, or both may be combined. Many ingenious devices have been invented by which the piano can be played automatically, the most successful of which is perhaps the *pianola*. The great advantage of this invention is the control which the player can exercise over expressive interpretation by means of fine dynamic shading

and modifications of tempo. But, like all mechanical contrivances, it has its shortcomings, as the inability to bring out a melody in the middle voices. The idea of dumb keyboards is quite old. The *digitorium* or *dumb piano* is a portable box having five keys supported on springs. The use of it has always been strongly condemned by good musicians. In 1883 Mr. Virgil of New York invented the *Virgil practice clavier*, which is now extensively used and has several points of excellence. It has a complete keyboard. Each key when pressed down gives an audible click. There is a mechanism by means of which the player is enabled to cause a second click upon the release of a key. This is of great advantage in the practice of a legato touch. The performer need only see to it that the two clicks, the one produced by the release of a key, the other by the depression of the next key, coincide exactly. By means of a mechanical adjustment the action can be regulated at will from the very lightest pianoforte touch (2 ounces) up to 20 ounces. If used with judgment this is an excellent device for acquiring strength of the fingers. For exercises of a purely technical nature, the clavier is a valuable help. Some standard works dealing with the history of the pianoforte are: Rimbault, *History of the Pianoforte* (London, 1860); Paul, *Geschichte des Klaviers* (Leipzig, 1868); Gontershausen, *Der Klavierbau* (Frankfort, 1870); Ponsicchi, *Il pianoforte, sua origine e sviluppo* (Florence, 1876); Blüthner and Gretschel, *Lehrbuch des Pianofortebaues* (Weimar, 1886); Spillane, *History of the American Pianoforte* (New York, 1890); Hipkins, *The Pianoforte* (London, 1896); Bie, *A History of the Pianoforte and Pianoforte Players*, trans. from the German (London, 1899). See HARPSICHORD; MONOCHORD; PANTALEON; SPINET; VIRGINAL.

PIARISTS (from Lat. *pius*, pious), or FATHERS OF THE PIOUS SCHOOLS. A religious congrégation for the education of the poor, founded at Rome at the end of the sixteenth century by Saint Joseph of Calasanza. He was a Spanish priest who, while in Rome, was struck with the imperfect and insufficient character of the education even of the higher classes, and decided to devote himself wholly to the meeting of this want. In 1597 he opened a school, with the assistance of a few like-minded friends, which rapidly increased until, seven years after, it numbered 900 pupils, and in 1613 as many as 1200. In 1617 the associates were recognized as a congregation by Paul V., who warmly approved the work. It spread during the seventeenth century into various European countries, and now numbers some 350 members, principally in Italy, Spain, and America. The general, who is chosen for nine years, resides in Rome, where general chapters are held every six years. The system of education adopted in their schools is very thorough, and in many ways resembles that of the Jesuits, with whom the Piarists have always had some affinity; on the suppression of the Society of Jesus they received many of its members into their ranks.

PIAS'SABA, or **PIAÇABA** (Port. *piassava*, *piaçab*, from the native Brazilian name). A remarkable and important vegetable fibre produced by one or more species of South American palms. The greater part is furnished by the coquilla nut palm (*Attalea funifera*), but Wallace states that much of it is produced from a species of Leopoldinia, which he has named *Leopoldinia piassaba*. This quality is known commercially as Para piassaba. When the leaves decay, the petioles split up into cylindrical, dark-brown hard fibres varying from the thickness of a horsehair to the size of a quill. This material has been widely used in making coarse brushes, particularly those required for street-sweeping machines, for which purpose the coarsest have almost superseded all other kinds. The smaller fibres are used for finer brushes. In Brazil, cables, baskets, hats, and many other articles are made from this fibre. Large quantities are exported.

PIATIGORSK, pyä'tê-gôrsk'. A town in Russia. See PYATIGORSK.

PIATRA, pyä'trä. A town of Moldavia, Rumania, situated on the Bistritza, about 55 miles southwest of Jassy (Map: Balkan Peninsula, F 1). It has a large number of churches and monasteries and is an important centre in the lumber trade. Population, in 1901, 17,391.

PIATT, pī'at, DONN (1819-91). An American lawyer and journalist. He was born in Ohio, was educated at Saint Xavier College, Cincinnati, studied law, and was in 1851 elected judge of the common pleas court. During President Pierce's administration he was secretary of the Paris Legation, and for some months was acting chargé d'affaires. He enlisted as a private at the outbreak of the Civil War, and rose to the rank of colonel of volunteers, having served for the greater part of the war as adjutant-general on General Schenck's staff. After the war he was a newspaper correspondent, and founded the Washington *Capital*. His publications include: *Memoirs of the Men Who Saved the Union* (1887); and the poem, *The Lone Grave of the Shenandoah* (1888). Consult Miller, *Life of Donn Piatt* (1893).

PIATT, JOHN JAMES (1835—). An American journalist and poet, born in Milton, Ind. After studies at Capital University and Kenyon College, he was connected with Louisville and Cincinnati journals, and in 1871 was chosen librarian of the House of Representatives. From 1882 to 1893 he served as United States Consul at Cork and Dublin, Ireland. His poems are collected under many titles, among which are: *Poems of Two Friends* (with W. D. Howells, 1860); *The Nests at Washington* (with Mrs. Piatt, 1864); *Poems in Sunshine and Firelight* (1866); *Western Windows* (1869); *Landmarks, and Other Poems* (1871); *Idylls and Lyrics of the Ohio Valley* (1884-88-92); *At the Holy Well* (1887); etc. His prose works are less striking than his description in verse of the sentiments that underlie life in the Middle West.—His wife, SARAH MORGAN (BRYAN), born in Lexington, Ky., August 11, 1836, is known for many volumes of verse. She issued her *Collected Poems* in 1894.

PIAUHY, pē'ou-ē'. A State of Northeastern Brazil, bounded on the east by the States of Ceará and Pernambuco, on the south by Bahia, on the northwest by Maranhão (Map: Brazil, J 5). On the Atlantic Ocean, on the north, it has a coast line of less than 10 miles. Area, 116,218 square miles. The surface consists mainly of sparsely wooded tablelands or *campos*, with lowlands in the north and west and along the rivers. There are no forests and the climate is dry and

hot. The chief rivers are the Paranahyba and its affluents. Agriculture is hindered by droughts and the scarcity of population, and the attempts to establish colonies of foreign immigrants have not been successful. Sugar, manioc, tobacco, and grain are raised in quantities hardly sufficient for domestic consumption. Cattle-raising is more extensive. Piauhy contains iron, aluminum, and some silver, but the deposits are not worked to any extent. The population was estimated in 1894 at over 300,000, mostly of mixed race. The capital is Theresina (q.v.), and the chief port is Paranahyba.

PIAZZA ARMERINA, pē-ät'sä är'mā-rē'nä. A town in the Province of Caltanissetta, Sicily, 18 miles southeast of Caltanissetta. It stands on the crest and slopes of an isolated hill on the left bank of the Terranova. It is the residence of many nobles and landowners. The town has a Renaissance cathedral (1517), an old castle now used as a prison, a gymnasium, a seminary, a technical school, a theatre, and a picture gallery. The trade is chiefly in corn, wine, oil, fruits, and nuts. Piazza Armerina was founded by the Greeks. It was destroyed in 1160, but was soon rebuilt. Population (commune), in 1881, 19,591; in 1901, 24,379.

PIAZZA DELLA SIGNORIA, dĕl'lä sē'nyō-rē'ä. See Florence.

PIAZZA DEL POPOLO, pō'pō-lō. See Rome.

PIAZZA DI SPAGNA, spä'nyä. A square in Rome named from the Palazzo di Spagna, the residence of the Spanish ambassador. It is the centre of the foreign colony. Its most noted feature is the famous Spanish steps, leading to the Church of the Trinità de' Monti, and the resort of picturesquely clad artists' models.

PIAZZA NAVONA, nä-vō'nä. The second largest public place of Rome, laid out on the site of the Stadium of Domitian, on the ruins of which the surrounding buildings rest. The piazza, officially called the Circo Agonale, corresponds in size and shape to the ancient stadium, and contains three fountains and an obelisk in honor of Domitian, originally in the circus of Maxentius.

PIAZZA VENEZIA, vā-nā'tsē-ä. See Rome.

PIAZZI, pē-ät'sē, Giuseppe (1746-1826). An Italian astronomer, born at Ponte. He is known principally for his work at Palermo, where he went in 1781 to take the chair of mathematics, and where he established an observatory, which was put in working order in 1789. The first results of his observations were the corrections of some errors in the estimation of the obliquity of the ecliptic, the aberration of light, the length of the tropical year, and the parallax of various heavenly bodies. These results were published in 1792. On the night of January 1, 1801, he discovered a new planet, the first known of the planetoids (q.v.). Piazzi was able to obtain only a very few observations of it before it passed too near the sun to be visible; from which Gauss (q.v.) was nevertheless able to compute its orbit so that it was again found later in the year. Piazzi named it Ceres, after the ancient goddess of Sicily. In 1803 he published a catalogue of the fixed stars, the result of ten years' observations and far superior to any before published. It was rewarded with a prize from the Institute of France. In 1814 appeared a new and more complete catalogue, containing 7646 stars, for which he was again rewarded with a prize from the French Institute. This catalogue is now regarded as his work of most lasting value to astronomy; and a new computation of his observations, using modern methods, is now being made. He also made researches into the nature of comets. In 1817 he was called to Naples as chief director of the Government Observatory, where he remained till his death.

PI-BESETH, pē-bā'sĕth. See Bubastis.

PIBROCH, pē'brŏk (Gael. *piobaireachd*, art of playing on the bagpipe, from *piobair*, piper, from *piob*, bagpipe + *fear*, Olr. *fer*, man, connected with Lat. *vir*, Lith. *výras*, Lett. *wirs*, Skt. *vīra*, Goth. *wair*, AS., OHG. *wer*, man). The highest form of music written for the bagpipe. It consists of a series of variations written on a fundamental theme called *urlar*. These variations (generally three or four in number) increase in difficulty and speed, the last one, *crunluidh*, being a furious *presto*. What renders the notation of pibrochs particularly difficult is the great number of ornaments introduced, so that no definite rhythm can be discovered. A still greater difficulty is encountered because they make use of the eleventh overtone (a tone between f and f♯), and thus cannot be reduced to any scale. Only in comparatively recent times (nineteenth century) has the expression of pibrochs in our notation been attempted. Before that, all music for the bagpipe was taught by a special system, the different tones having such names as *hodroho*, *hananin*, *hiechin*, etc. Niel Macleod published in 1828 at Edinburgh a collection of pibrochs in this peculiar notation. See Bagpipe.

PICA. See Printing.

PICAN'DER. The pseudonym of the German poet Christian Friedrich Henrici (q.v.).

PIC'ARD. A corruption of Beghard. See Beguines.

PICARD, pē'kär', Jean (1620-82). A French astronomer. In 1655 he succeeded Gassendi as professor of astronomy in the Collège de France. In 1666 he became a member of the Academy of Sciences. In 1671 he went to Uranienborg, on the island of Hven in the Sound, to determine the latitude and longitude of Tycho Brahe's observatory. The Paris Observatory and the *Connaissance des Temps* were founded by his efforts. He is known especially for his geodetic work in connection with determining by measurement the exact length of a degree of latitude.

PICARD, Louis Benoit (1769-1828). A French dramatist, born in Paris. He began early to write plays, the first of which was *Le badinage dangereux* (1789). In many that he subsequently produced, he was both author and actor, and he had several collaborators. His plays, excellent pictures of the time, are satirical and vivacious, and have animated dialogue. The best include: *Encore des méprises* (1791), which made his reputation; *Médiocre et rampant* (1797); *Les marionnettes* (1807); *Les capitulations de conscience* (1809); and *L'intrigant maladroit* (1820). Several of them are printed in his *Théâtre* (8 vols., 1821) and *Théâtre républicain* (1832).

PIC'ARDY (Fr. *Picardie*). Formerly a province of France, now constituting the Department of Somme and parts of the departments of

Pas-de-Calais, Aisne, and Oise. Its principal town was Amiens. In 1167 Philip of Alsace, Count of Flanders, became Count of Picardy. It was acquired by Burgundy in 1435 and was united to France in 1477.

PIC'CADIL'LY. An important London street extending for about a mile between the Haymarket and Hyde Park Corner. One portion of the street contains many handsome shops, while the other is given up to fashionable residences. The name is referred to a kind of lace, fashionable in Queen Elizabeth's time, or to the collars so called during the reign of James I.

PICCINI, or **PICCINNI,** pē-chē'nē, Niccolò (1728-1800). An Italian composer. He was born in Bari, and studied music with Durante and Leo at the Conservatory of Sant' Onofrio, Naples. After producing a number of operas at Naples he removed to Rome, where he brought out *Allessandro nell' Indie* (1758); *Cecchina zitella, ossia la buona figliuola* (1760), which had an unparalleled success; and *L'Olimpiade* (1761). In 1776 he went to Paris, where Gluck was then the popular composer. Marmontel and others championed Piccini, and for several years a bitter controversy was carried on between the 'Piccinists' and the 'Gluckists.' Marmontel made a modern version of Quinault's drama *Roland*, and Piccini composed an opera on it, which had great success. He also composed *Iphigénie en Tauride*, a subject on which Gluck had also written an opera, *Atys*, and many others. He was professor in the Ecole de Chant (1783-91), was removed, and returned to Naples, where he suffered much annoyance from the espionage of the Government on account of his supposed revolutionary sympathies. Returning to Paris in 1798, he succeeded in obtaining from Bonaparte the inspectorship of music at the National Conservatory, but he did not live to begin the duties of his office. He is of interest to the musical historian, not so much for the quality of his work, or his ability as an artist, as for the important part he played in the overthrow of Logroscino (q.v.), whose buffo operas were then the vogue in Naples; and his own defeat (together with the ideas for which he stood) by Gluck (q.v.). He died at Passy, near Paris.

PICCININO, pē'chē-nē'nō, Nicolà (1375-1444). An Italian soldier, born at Perugia. He entered the band of condottieri led by Braccio da Montone, and after the death of their chief was elected to succeed him. For a short time he served Florence, but in 1425 went over to Filippo Maria Visconti, of Milan. Fighting in his interest, he defeated Carmagnola and the Venetians at Soncino and at Cremona (1431), and at Imola in 1434 gained a victory over the Venetians and Florentines. He captured Bologna in 1438. The city revolted from Piccinino's rule in 1443, and, overcome by reverses and the loss of his son, he died in the next year.

PICCIOLA, pēt'chō-lä. A pathetic story by Saintine (1836) which attained wide popularity and brought the author a decoration and the Montyon prize. It is the story of a prisoner in the time of Napoleon I., who beguiles the monotony of his confinement by caring for a plant which springs up between the stones of his cell, and which he calls *Picciola* (poor little one). The prisoner's life is saved in sickness by an infusion of the leaves of the plant, which withers and dies after his release.

PIC'COLO (It., small). A flute of small dimensions, having the same compass as the ordinary flute, while the notes all sound an octave higher than their notation. In joyous as well as violent passages this instrument is sometimes very effective in an orchestra. The piccolo is usually made in three keys, C, D♭, and E♭, the latter two being used almost exclusively in military music. Piccolo is also the name of an organ stop. See Flute.

PICCOLOMINI, pik'kō-lōm'i-nē. The name of an old Italian family, whose ancestors settled at Rome, afterwards removed to Siena, and finally obtained the Duchy of Amalfi. Its most eminent member was Æneas Sylvius Piccolomini, who became Pope in 1458. (See Pius II.) The family also gave several cardinals to the Church, and another pope, Pius III. (q.v.).—Ottavio Piccolomini (1599-1656), first Duke of Amalfi, and fifth in direct descent from Pope Pius II., was a distinguished general in the Thirty Years' War on the Catholic side. He first entered the Spanish military service, and then as captain in a Florentine cavalry regiment aided Emperor Ferdinand II. against the Bohemians. He won distinction as a cavalry leader, served under Wallenstein, and at Lützen (1632) commanded the regiment of cuirassiers that met the last charge of Gustavus Adolphus. Wallenstein confided to him his secret designs against the Emperor; Piccolomini, however, communicated these designs to the Emperor, and after Wallenstein's assassination (1634) received as a reward for his fidelity a part of his estates. He took part in the battle of Nördlingen (1634), and in the following year was sent with a large force to aid the Spaniards in the Netherlands, where the French and Dutch were carrying all before them. Piccolomini speedily drove out the French, but his success against the Dutch was not so marked. In 1640 he was summoned to stay the Swedes, under Baner, who were threatening the hereditary possessions of Austria. He succeeded in checking the invaders in Bohemia and the Palatinate, but was badly beaten, along with the Archduke Leopold, in 1642 at Leipzig by Torstenson. He was now sent to the Netherlands to take command of the Spanish troops, and though the prestige of the Spanish infantry was destroyed by the Duke d'Enghien (the future Condé) at Rocroi (May 19, 1643), Piccolomini was again successful against both the French and Dutch until 1648, when he was anew summoned to Germany to encounter the victorious Swedes. The Peace of Westphalia put an end to the Thirty Years' War soon after. Piccolomini had now attained the rank of field marshal. In 1650 [illegible] to the dignity of [illegible] King of Spain conferred [illegible] the Golden Fleece [illegible] Duchy of Amalfi, which [illegible] to his family. With [illegible] Piccolomini [illegible] 7, 1656.

PICCOLOMINI. Die [illegible] second play in Schiller's Wallenstein trilogy, produced in 1799. It represents Wallenstein in the midst of his preparations to make himself master of the throne of Bohemia, and takes its name from the two Italians, Octavio and Max Piccolomini. Max,

the son, is [illegible] adherent of Wallenstein, while Octavio, the professed friend on whom Wallenstein relies, is in reality employed by the Emperor to watch him. Octavio in *Die Piccolomini* gradually involves Wallenstein in the web which leads to his death in the third tragedy of the series, *Wallensteins Tod*.

PICHEGRU, pēsh'grȳ'. CHARLES (1761-1804). A French revolutionary general. He was born February 16, 1761, at Arbois, in the Department of Jura, and was educated at the college of his native town. He subsequently attended the military academy at Brienne, where he taught mathematics and had Bonaparte as one of his pupils. He entered an artillery regiment in 1783 and was for a short time in America. He was lieutenant when the Revolution broke out. Pichegru became an ardent republican, joined the army of the Rhine, and by his soldierly qualities soon attracted general attention and earned rapid promotion. In 1793 he became general of division and commander of the Army of the Rhine, and, in conjunction with the Army of the Moselle under Hoche, repeatedly defeated the Austrians and established himself securely in the Palatinate. After the arrest of Hoche, his success at the head of the combined Rhine and Moselle armies was not less decided. The rapidity and boldness of his manœuvres when in command of the Army of the North, in 1794, again disconcerted the Allies, and they were compelled to retreat beyond the Meuse. Pichegru completed the conquest of Holland in 1795 and ended a glorious campaign by organizing the Batavian Republic. He next visited Paris, and while there suppressed an insurrection in the suburbs of the city (April 1, 1795); but soon afterwards went to take command of the Army of the Rhine, and for some time displayed his usual skill and energy, crossing the river in the face of the enemy and capturing the fortress of Mannheim. But the state of affairs at Paris, combined with the flattering promises and bribes held out to him by the Prince of Condé, converted Pichegru into a secret partisan of the Bourbons. His inactivity, though prearranged with the Austrian generals, was not suspected till he suffered himself to be defeated at Heidelberg, and retreated, leaving Jourdan (q.v.) without support, thus compelling the latter also to retire. The suspicions of the Directory were confirmed by the seizure of Pichegru's correspondence, and he was immediately superseded by Moreau (q.v.). He then retired to his native town, where he lived till 1797, when he was elected one of the Council of Five Hundred. He soon became its president; but still continuing his intrigues with the Bourbons, he was arrested, and subsequently transported to Cayenne, but escaped in June, 1798, to England. He entered heart and soul into the Bourbon conspiracy along with Cadoudal (q.v.), the two Polignacs, and others, the primary object of which was the assassination of the First Consul. The conspirators secretly reached Paris, and there in 1804 Pichegru attempted to persuade Moreau, who was on bad terms with Napoleon, to join them, but without success. But the plans of the conspirators were soon known to the police, and an intimate friend of Pichegru, with whom he resided, sold the secret of his retreat to the police. Pichegru was suddenly arrested and taken to the Temple prison February 28, 1804. On April 6 he was [illegible] dead in his bed. The Royalists endeavored to fasten a charge of secret assassination on Napoleon, but it was generally, and probably correctly, believed that Pichegru strangled himself. Consult the biographies by Gassier (Paris, 1814), Pierret (ib., 1826), Vouziers (Dôle, 1870); also Montgaillard, *Mémoire, concernant la trahison de Pichegru* (Paris, 1804); and Daudet, *La conjuration de Pichegru, etc.* (ib., 1901).

PICE'NUM. One of the ancient divisions of Middle Italy, extending along the Adriatic from the Aesis (now Esino) to below the Vomanus (now Vomano) River and bounded on the west by Umbria, Sabinum, and Vestinum. It was anciently inhabited by the Umbrians, who were conquered by the Sabines, under whom the name Picenum was acquired. In 268 the district was reduced by the Romans to the condition of a dependency and many of its inhabitants colonized in the town of Picentia. In Aeculum, the old capital of Picentum, in B.C. 91, occurred the outbreak of the war of the Italian Confederacy against Rome. Under Augustus Picenum formed the fifth political region of Italy.

PICHICIAGO. See ARMADILLO and Plate of ANT-EATERS.

PICHINCHA, pē-chēn'chä. A volcano of the western range of the Andes in Ecuador, situated a few miles northwest of Quito (Map: Ecuador, B 4). It is an irregular mass of peaks, the highest of which, Huahua-Pichincha, has an altitude of 15,918 feet. Its crater is over 2000 feet deep; it is dormant, there having been no great eruption since 1660. On its slopes, on May 24, 1822, was fought the battle which secured the independence of the Republic.

PICHLER, pĭk'lẽr, ADOLF VON (1819-1900). An Austrian poet and naturalist. He was born at Erl in Tyrol, studied at Innsbruck and Vienna, published his first volume of poems in 1846, and in 1848 fought as an Austrian volunteer in the Italian campaign with great bravery. In 1867 he was appointed professor of mineralogy and geology in the University of Innsbruck. He wrote on the geology of the Alps and of Tyrol, but is better known as the Tyrolese poet, author of *Frühlieder aus Tirol* (1846), *In Lieb' und Hass* (1869; 3d ed. 1900), *Vorwinter* (1885), and *Spätfrüchte* (1896). Valuable autobiographic material is contained in his *Aus den März- und Oktobertagen zu Wien, 1848* (1850), and *Aus dem welsch-tirolischen Kriege* (1849). Consult Prem, *Adolf von Pichler, der Dichter und Mensch* (Innsbruck, 1901).

PICHLER, KAROLINE (1769-1843). An Austrian novelist, born in Vienna. Her first novels, *Gleichnisse* (1800), *Olivier* (1802), *Leonore* (1804), *Ruth* (1805), possessed slight merit; *Agathokles* (1808), her best work, was meant to disprove the heresies of Gibbon's *Decline of the Roman Empire*. Succeeding novels were chiefly historical in matter, patriotic in purpose, and diffuse in style; e.g. *Die Grafen von Hohenburg* (1811), *Die Belagerung Wiens* (1824), *Die Schweden in Prag* (1827), *Henriette von England* (1832). She also wrote society stories, *Franenwürde* (1808), *Die Nebenbuhler* (1821), *Zeitbilder* (1840), which, like her autobiographical *Denkwürdigkeiten* (1844), are wearisome. Her works are in 60 vols. (1845).

PICHU'RIC ACID. See LAURIC ACID.

PICIDÆ, pĭs′ĭ-dē (Neo-Lat. nom. pl., from Lat. *picus*, woodpecker). The family of woodpeckers (q.v.).

PICK, Bernhard (1842—). A Lutheran clergyman, born at Kempen, in Prussia. He studied in Berlin and at the Union Theological Seminary, New York City. In 1868 he entered the Presbyterian ministry, and, after having held several pastorates in that Church, he joined the Lutheran denomination in 1884. Besides contributing to the *Cyclopædia of Biblical, Theological, and Ecclesiastical Literature*, the *Cyclopædia of Religious Knowledge*, and many periodicals, his publications include: *Luther as a Hymnist* (1875); *Life of Christ According to Extra-Canonical Sources* (1887); and *The Talmud, What It Is and What It Says About Jesus and the Christians* (1887).

PICKELHERING, pĭk′el-hā′rĭng. A stock fool in the drama. The name was probably first assumed in the early part of the seventeenth century by Robert Reynolds, who traveled through Germany with a company of strolling comedians, and created a type which maintained itself until the eighteenth century.

PICK′ENS, Andrew (1739-1817). An American soldier, born at Paxton, Pa. He removed with his parents to the Waxhaw settlement, S. C., in 1752, and fought in the Cherokee war in 1761 as a volunteer. At the beginning of the Revolutionary War he became captain of a militia company, and by successive promotions soon attained the rank of brigadier-general of South Carolina troops, gaining great distinction as a partisan leader. In 1779 he defeated a superior force of loyalists under General Boyd at Kettle Creek, participated on June 10th in the battle of Stono Ferry, and defeated the Cherokees at Tomassee. He commanded the militia at the battle of Cowpens, January 17, 1781, twice rallying them after they had been driven back, and for his gallantry received a sword from Congress. At the battle of Eutaw Springs, September 8, 1781, he was in command of the Carolina militia, and in 1782 forced the Cherokees to relinquish their claim to a large tract of land now included in the State of Georgia. After the war he was a member of the South Carolina Legislature from 1783 to 1794; sat in Congress in 1793-95; was a member of the State Constitutional Convention; became major-general of militia in 1795; and was again in the Legislature in 1801 and 1812. He was commissioner on many occasions to treat with the Indians. His son, Andrew, a lawyer, was Governor of South Carolina in 1816-18, and died in Mississippi in 1838.

PICKENS, Fort. See Fort Pickens.

PICKENS, Francis Wilkinson (1805-69). An American statesman and diplomat, born at Togadoo, Saint Paul's Parish, S. C. He studied at South Carolina College, was admitted to the bar in 1829, and three years afterwards was elected to the State Legislature, where he soon became prominent as an advocate of nullification and the doctrine of extreme States' rights. From 1834 until 1844 he was a member of Congress, in 1850-51 a delegate to the Nashville Southern Convention, and in 1854 presiding officer of the South Carolina State Convention, and in 1856 a delegate to the General Democratic Convention in Cincinnati. The next year he was appointed United States Minister to Russia, but returned to America in 1860, and soon afterwards was elected Governor of South Carolina. He zealously supported the secession movement, and immediately after the passage of the ordinance by the Charleston Convention began to organize an independent government. To this end he demanded the surrender of all Federal property within the borders of the State, and when Major Anderson refused to give up Fort Sumter, began to erect the batteries which afterwards, under the orders of the Confederate Government, caused its reduction.

PICKEREL (double diminutive of *pike*). One of the smaller members of the pike family, Luciidæ. The Eastern or pond pickerel, jack, or green pike (*Lucius reticulatus*) is common everywhere east and south of the Alleghany Mountains. In Tennessee and Arkansas it reaches a length of 24 inches and is golden green marked with numerous dark lines and streaks, which are mostly horizontal, and by their junction with one another produce a reticulated appearance. The banded pickerel (*Lucius Americanus*), of the coast streams from Massachusetts to Florida, is 12 inches long and dark green, with about 20 blackish curved bars on the sides. The little pickerel (*Lucius vermiculatus*) occurs throughout the Mississippi Valley, is 12 inches long and very variable in color, with an irregular network of fine curving streaks on the sides. The common pike is also frequently called 'pickerel.' The habits and mode of catching are the same as in the case of the pike (q.v.). See Plate of Needlefish, Pikes, etc., and Colored Plate of American Game Fishes, accompanying article Trout.

PICKEREL FROG. A small light brown frog (*Rana palustris*) with dark square or oblong brown blotches in two rows on its back, and the head marked by a dark line which runs from the nostril to the eye. This frog dwells in the Eastern United States, especially in mountainous parts, and occurs mainly about springs.

PICK′ERING, Charles (1805-78). An American naturalist, grandson of Col. Timothy Pickering, born at Starucca Creek, Pa. He graduated at Harvard in 1823, and at the Medical School three years later. After practicing for some years he was, in 1838, appointed naturalist of the United States Exploring Expedition under the command of Lieut. Charles Wilkes (q.v.). In 1843 he visited Egypt, Arabia, East Africa, and India. He published: *The Races of Man and Their Geographical Distribution* (1848); *The Geographical Distribution of Animals and Plants* (1854); and *The Chronological History of Plants: Man's Record of His Own Existence Illustrated Through Their Names, Uses, and Companionship* (1879).

PICKERING, Edward Charles (1846—). An American astronomer, born in Boston. He graduated at the Lawrence Scientific School, Harvard, in 1865, and for the next two years was instructor of mathematics there. From 1867 until 1877 he was Thayer professor of physics at the Massachusetts Institute of Technology, but in the latter year he was appointed professor [illegible] observatory. At the Institute of Technology he, in 1870, established the first physical laboratory for general instruction in the United States, and later, in connection with his work at Harvard, established an

observatory at Arequipa, in Peru. He devoted particular attention to the study of light and the spectra of the stars and published the results of his observations in the *Annals of the Harvard Observatory*. He also wrote *Elements of Physical Manipulation* (1874).

PICKERING, John (1777-1846). An American linguist and lexicographer, son of Timothy Pickering, born in Salem, Mass. He graduated at Harvard in 1796, studied law with Edward Tilgham in Philadelphia, was Secretary of Legation in Lisbon until 1799, and then became private secretary to Rufus King, Minister to England. He practiced law in Salem, Mass., from 1801 to 1827, was City Solicitor of Boston (1827-46), and during his service in the State Legislature took a prominent part in revising the Massachusetts general statutes. He was president of the American Academy of Sciences, first president of the American Oriental Society, an able linguist, and, like his father, particularly interested in the languages of the North American Indians. He wrote *A Uniform Orthography for the Indian Languages* (1820), *Remarks on the Indian Languages of North America* (1836), *Vocabulary of Words and Phrases Supposed to Be Peculiar to the United States* (1816), and a *Greek and English Lexicon* (1826, 3d ed. 1846), as well as many monographs on ancient and international law. Consult the biography by his daughter, Mary Orne Pickering (Boston, 1887).

PICKERING, Timothy (1745-1829). An American statesman. He was born at Salem, Mass., July 17, 1745, graduated at Harvard in 1763, and was admitted to the bar in 1768. In 1773 he drafted for the town of Salem a paper entitled *State of the Rights of the Colonists*, and in the following year the memorial of the citizens of Salem to General Gage in regard to the Boston Port Bill. In 1776 he joined the Revolutionary Army and led an Essex County regiment to Tarrytown, N. Y. In the following year he took part in the battles of Brandywine and Germantown, and was appointed a member of the Congressional Board of War. In 1780 he was appointed Quartermaster-General of the army and retained the office until its abolition in 1785. Upon his retirement from the army, he engaged in business in Philadelphia, but two years later removed to the Wyoming Valley and became involved in the disturbances of that region, where he was instrumental in maintaining order and quiet. He settled the territorial disputes between Pennsylvania and the inhabitants of the Wyoming Valley, and organized Luzerne County, which he represented in the Pennsylvania Constitutional Convention of 1789. In 1790 he was commissioned by President Washington to negotiate a treaty with the Six Nations, which he did successfully, and later performed a similar service with the Indians of the Northwest. In 1791 Colonel Pickering was appointed Postmaster-General of the United States, which office he held until 1795, when he was appointed Secretary of War. Pickering signalized his administration by establishing a military school at West Point and by supervising the construction of the frigates *Constitution*, *United States*, and *Constellation*. Upon the resignation of Edmund Randolph near the end of 1795, Colonel Pickering was appointed Secretary of State, which office he held during the remainder of Washington's term and through the greater part of Adams's administration. In 1800 he was abruptly removed on account of a serious disagreement with the President growing out of the difficulties with France over the X. Y. Z. correspondence (q.v.). He then retired to his uncleared lands in what is now Susquehanna County, Pa., but was in poor circumstances, and some of his Massachusetts friends prevailed upon him to return to his native State, where in 1802 he became Chief Justice of the Court of Common Pleas. In the following year he was elected to the United States Senate, where he served until 1811. As a member of the House of Representatives he served until 1817, when he refused a renomination and again retired to private life. He died at Salem, January 29, 1829. Pickering wrote numerous political papers, including a *Review of the Correspondence Between John Adams and William Cunningham*. A biography of Colonel Pickering in 4 vols. was published by Octavius Pickering and C. W. Upham (Boston, 1867-73).

PICKERING, William (1796-1854). An English publisher. After serving for ten years in a Quaker publishing house in Cornhill, London, he opened a bookshop of his own in Lincoln's Inn Fields (1820). Adding publishing to the business, he subsequently moved to Chancery Lane (1824) and to Piccadilly (1842). For printing he employed the Chiswick Press. About 1830 he adopted the trade-mark of Aldus, the famous Italian printer—an anchor entwined with a dolphin, to which was added the motto, *Aldi Discip. Ang.* Among his notable undertakings were the "Diamond Classics" (a series of delicate volumes in 48mo and 32mo, issued between 1821 and 1831); and reprints of different versions of the Book of Common Prayer between 1549 and 1662 (6 vols., 1844), the typography of which has probably never been surpassed. Among his sumptuous publications may be cited Walton's *Compleat Angler*, illustrated by Stothard and Inskipp (2 vols., 1836). He also projected the Aldine edition of English poets. After his death the business was carried on by his son, Basil Montague Pickering (1836-78), who, among several reprints, issued a facsimile of the first edition of *Paradise Lost*. In 1878 the firm came to an end.
